#### Abstract

A promising, supplementary material, highly reactive silica nanoparticles tend to react with calcium species ( $\text{Ca}^{2+}$ ) in cement, which produces more hydrated phases. The high amount of calcium species and the potential of capturing carbon dioxide ( $\text{CO}_2$ ) through carbonation implies the suitability of cement paste as a  $\text{CO}_2$  sorbent material. However, limited studies could be found highlighting the effect of silica nanoparticle inclusion on the  $\text{CO}_2$  capture property of hardened cement paste. Thus, this study investigates the effect of silica nanoparticle partial replacement on the  $\text{CO}_2$  capture capacity and regeneration performance of hardened cement paste. XRD and SEM analysis proved the formation of more hydrated phases upon partially replacing silica nanoparticles in cement. Partial replacement of 3.00 % with silica nanoparticles significantly improved  $\text{CO}_2$  regeneration capture at room temperature among the other cement paste samples. This study found that the presence of silica nanoparticles in cement paste triggered the formation of more hydrated phases, which served as active sites for  $\text{CO}_2$  capture to occur and, thus, improved the  $\text{CO}_2$  capture capacity and regeneration performance. © (2024), (International Islamic University Malaysia-IIUM).
