Abstract

Loops are of different types, for loop, do loop and do-while loops. Each of these loops differs in order of executions of instructions embodied inside the loop structures.

11.1 Program for while loop exercise

Assuming you have a program to run many times the foremost important is to decide which of the variables can be selected as loop control variable. The loop control variable is then the one to be used to execute the program segment as specified. The example for loops is provided in Figure 11.1. Loops always relinquish executions using controls.
