ABSTRACT

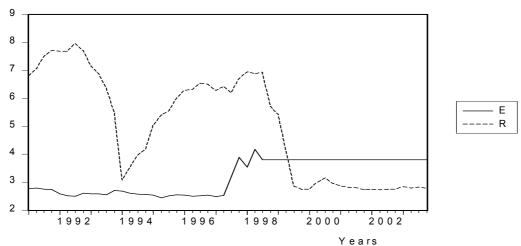
The objective of this paper is to estimate and test the stability of money demand function in Malaysia using the cointegration and error-correction techniques on a quarterly data on real money balances, real output, real exchange rate and interest rates on Government securities, from 1991:I to 2003:4. The cointegration tests indicate that both M1 and M2 are cointegrated with the specified independent variables. The estimated vector error-correction system supports a single cointegrating equation and a stable long-run real money demand function in Malaysia. The coefficients on all the variables carry correct signs and are significant (except the coefficient on real exchange rate). The finding of strong causality running from money (both narrow and broad) to output affirms the critical importance of money as an important instrument for reviving the economic activity in the short run. The Granger-causality implied by this result is compatible with Keynesian and Monetarist macroeconomic theoretical foundation that money is not neutral in the short run. The findings indicate that M2 has the strongest causal effect on the real output. Finally, the finding of a single stable long-run money demand function has important policy implication for Malaysia in that if the central bank wants to control the total liquidity in the economy, it can do so by identifying appropriate medium-term growth targets for money supply and manipulate interest rates and reserve money.

INTRODUCTION

In the mid of 1997, the East Asian economies suffered their worse crises which were sparked off by speculative attacks on their currency and equity markets. Goldstein and Hawkins (1998) group the sources of these crises into (i) financial-sector vulnerabilities such as poor credit assessment in some emerging Asian economies with relatively easy global liquidity conditions, (ii) external-sector problems which generated some concerns about balance of payments developments, and (ii) contagion from Thailand which quickly spread to its immediate neighbors (Indonesia, Malaysia and Philippine) and then to South Korea, Taiwan, Hong Kong and Japan. This contagion appeared to have emerged from the realization by the market that a number of Asian economies had the same vulnerabilities as Thailand whose currency, the Baht, had plummeted in May 1997.

Speculators took the action when they felt that the depreciation of these countries' currencies was due to disequilibria in macroeconomic variables after almost a complete decade of high growth. Particularly, the second half of 1997 and the first week of September witnessed steep declines in the US dollar exchange rates of the Asean-4 (Indonesia, Malaysia, Philippine and Thailand). The worst affected was the Indonesian rupiah which lost a fifth of its pre-June 1997 value against the greenback. In Malaysia the crisis culminated in the depreciation of the national currency, the ringgit, by about 95 percent, from its par value of RM2.5 per US dollar before July 1997, to about RM4.88 per US dollar in January 1998. Between July 2, 1997 and September 2 1998, the ringgit plummeted to a record low of RM4.86 to the U.S. dollar (on January 7, 1998). Other Asian economies of Singapore, South Korea, Hong Kong and Taiwan currencies experienced moderate state of crisis.

In the aftermath of the crises, a number of important developments are worth noting. In the first place, the Asean-4 countries and South Korea had increased interest rates during 1996 as means of curbing credit growth or supporting their exchange rates. It is being argued[1] that these high interest rates increased the vulnerability to attacks as the speculators' strenuous efforts to push up the cost of 'holding on' to exchange rate commitment begun from a relatively high base. Secondly, as the pressures on exchange rate markets continued to intensify, each of the Asean-4 countries further increased short-tern interest rates aimed at preventing those pressures from intensifying further. Thirdly, in order to control the crises from getting out of hand, each Asean-4 countries resorted to a mixture of administrative measures, taxes and moral suasion with view to discouraging capital outflows and short sales of both the domestic currency and domestic equities and at reducing the need for even larger increases in domestic interest rates. On September 2 1998, the Malaysia government introduced a ban on

---


[1] See Goldstein and Hawkins (1998).

short selling of equities, although it was lifted shortly. A $20 billion plan to support the stock prices was also introduced, under which shares sold by Malaysians to state and investment funds would receive a premium whereas equities sale by foreigners would take place at market prices. Capital controls and the pegging of the Malaysian currency to the US dollar at MYR 3.80/US $ were important components of these measures. How the exchange and interest rates would have behaved in the second half of 1998 in the absence of these administrative measures is a matter of debate. However, one important thing that remains clear is that these measures did not prevent Asean-4 exchange rates from declining nor did they prevent the need for domestic interest rates from rising steeply. Figures 1 and 2 show these economic developments during 1991:1 to 2003:4.

Figure 1: Logarithmic Values or Real M1, real M2 and real GDP over 1991:1-2003:4.

Figure 2: Exchange rates and Interest rates over 1991:1-2003:4.

The conjecture posited in this paper is that such remarkable developments are likely to introduce structural instability in money demand function in an economy. It is generally believed that the financial innovations of the 1970s (money market accounts, NOW accounts, electronic transfers) might have changed the working definitions of money even though the official definitions remain unchanged. These developments provide sufficient *apriori* reasons for hypothesizing that money demand function would likely exhibit some instability. Hossain (1993) and Butkiewicz and McConnell (1995) report some evidence relating the effect of financial deregulation and reforms to instability in money demand functions in Bangladesh and US respectively.

The objective of this paper is to estimate and test the stability of money demand function in addition to examining the short-run dynamics as well as the long-run relationship between macro-variables and money demand in Malaysia. To achieve this objective, the paper will fit the Johansen multivariate cointegration and vector error-correction technique on quarterly time-series data on real money demand (M1 and M2), real output as a scale variable, real exchange rate and interest rates on government securities over the period from 1991:1 - 2003:4. The rest of the paper is arranged in sections as follows. Section II examines the literature on previous study of money demand function while Section III presents the empirical model and econometric methodology used to estimate the empirical model. Section IV contains the empirical results and their discussion whereas section V presents the paper conclusions and policy implications.

LITERATURE ON PREVIOUS STUDIES

The stability of money demand function is an important element in the conduct of monetary policy if central banks are to rely on money demand function for accurate identification of the medium-term growth targets for money supply and the manipulation of interest rates and reserve money to control total liquidity in the economy. An application of unstable money demand function for forecasting could produce unpredictable monetary growth rates and interest rates that might be inconsistent with development objectives in the real economy. For this, it is important that monetary authorities have a complete knowledge of the factors that affect the demand for money and certain about the existence of stable and predictable stable long-run relationship between the stock of money and these factors. A voluminous literature has accumulated as a result of many theoretical and empirical studies carried out in many countries with aim of identifying the determinants and testing the stability of money demand function.

Money demand theories can be loosely grouped into the Classical theory that went from the quantity theory through the so-called equation of exchange to Cambridge equation, (Fisher, 1911; Pigou, 1917; and Marshall, 1923); Keynesian theory (Keynes, 1936), which is based on the famous transactions, precautionary, and the speculative motives for holding money; the monetarist theory (Friedman, 1956) which is based on the general theory of asset demand and the permanent income theory; and finally, the portfolio theories which treat the quantity of money demanded as the outcome of a decision to allocate a fixed amount of wealth. A number of studies (Friedman, 1956 and Friedman and Schwartz, 1991) have shown that money demand function assumes a remarkably stable stationary long-run relationship between real money balances, real income, and the opportunity cost of holding real balances until mid-1970s. However, the stability of M1 demand function started to break down from 1970s. As a result, existing money demand functions were over-predicting money demand. The phenomenon, dubbed as the case of "missing money[2]" presented a major challenge for policymakers and researchers that relied on these functions for predicting the effect of monetary policy.

The apparent breakdown of M1 demand function in the 1970s and subsequently, M2 in 1990s, sparked off increasing interest in re-specifying money demand functions, using different components of money stock. Consequently, a number of studies, for example, Koĝar (1995), Shen and Huang (1999), Georgopoulos (2000), Slok (2002) and Ho (2003), find that M1 money demand function is more stable than any other component of money stock. However, Haug and Tam (2001) show that linear specification with M0 provides better fit than M1 whereas Hayo (2000) finds that while M1 money demand function was unstable, M2 money demand function displays long-run stability. Nevertheless, a number of studies have estimated broad money demand functions and find strong long-run stability of such functions. For example, Coenen and Vega (1999), Nachega (2001), Paustian *et al* (2001), Jonsson (2001), Meshach (2002) and Bruggeman *et al* (2003) confirm the existence of a sufficiently stable long-run relationship between broad money demand and the specified independent variables.

THE EMPIRICAL MODEL AND METHODOLOGY

Long-run demand for money, whether derived from Keynesian theoretical models relating to the transaction demand theory (e.g., Baumol, 1952; Tobin, 1956; Laidler, 1984), Monetarist models based on the quantity theory of money (Friedman and Schwartz, 1982) or the portfolio balance approach (Tobin, 1968), is positively related to the price level, P, and income and/or wealth, Y and negatively to its opportunity cost, the own interest rate(s), R. Following Nachega (2001) and Meshach (2002), the demand for money, which is a choice between alternative real assets and financial assets available to wealth holders, is specified as follows:

$$(M^d / P) = f(Y, R) \tag{1}$$

where

M^d = demand for nominal money balances;
P = the price level;
Y = scale variable (income, wealth, expenditure, in real terms); and
R = vector of expected rates of return (within and outside broad money).

The above specification, which represents the long-run real money demand function, assumes a long-run unitary elasticity of the nominal cash balances with respect to the price level. The function is assumed to be increasing in both Y and the rates of return associated with assets included in M and decreasing in those elements of R representing rates of return on alternative assets.

---

[2] See Goldfield (1976).

In most empirical work, β_1 is found to be unity so that price homogeneity is imposed in order for the model to become the demand for real money balances. Furthermore, Huang et al (2001) argue that, in the long run, the demand for money, in open economies, depends mainly on real income and interest rates, in addition to exchange rates. As a result, the above model can take this alternative log-linear form with exception of interest rate as follows:

$$(m^d - p)_t = \beta_0 + \beta_1 y_t + \beta_2 e_t + \beta_3 R_t + \varepsilon_t \tag{2}$$

Where ε_t is the error term. With lower-case letters representing the logarithm of a variable, m_t is the log of real money supply in period t, y_t is the log of real GDP in period t, e_t log of real exchange rate at period t and R_t is the interest rate at period t. The expected signs for the β_i's are $\beta_1 > 0$, or specifically, $\beta_1 = 1$ for the quantity theory or $\beta_1 = 0.5$ for the economies of scale (Baumol-Tobin model), $\beta_2 < 0$ or > 0, and $\beta_3 < 0$. This model depicts an equilibrium relationship such that for given values of the right-hand side variables and their long-run impact on money demand (i.e., the β_i), money demand is at m^d. The equation assumes an instantaneous adjustment of real money demand and real money supply, although this equilibrium is unlikely to exist in presence of transactions cost and uncertainty[3]. The empirical analysis is carried out using annual time-series data on consumer price index (P_t), real money supply (M_t), interest rate (R_t), real exchange rate (E_t), and real output (y_t) over the sample period 1991:1-2003:4. A dummy variable is included with value 1 before 1998:3 and zero otherwise. All the variables are expressed in log form (except interest rate) and seasonally unadjusted.

The frequent failure of many researchers to investigate time-series properties of the data used and to examine the presence or absence of long-run relationships among the variables is invariably cited as the main reason for such inconclusive and mixed results. The use of the recently popularized cointegration technique has provided some relief in that it clearly identifies multiple cointegrating relationships among the variables, in addition to distinguishing between exogenous and endogenous variables. The technique is based on three important steps. First, prior to testing for cointegration, the properties of individual time series are investigated. This is done by applying the Augmented Dickey-Fuller (ADF) and the Phillip-Perron (PP) tests for detecting the presence or absence of unit roots in the variables. Estimating vector error-correction mechanism (VECM) requires that the data used be stationary because regression s involving nonstationary data may produce spurious results. Secondly, Johansen maximum likelihood method (Johansen, 1988 and Johansen and Juselius 1990) is used to examine the question of cointegration in a multivariate setting. If the variables are cointegrated, then tests involving differenced variables will be mis-specified and some important information will be lost unless the lagged error-correction term is included. While cointegration can indicate the presence or absence of Granger-causality, it does not indicate the direction of causality among the variables. It is only through this vector error-correction mechanism (VECM), derived from long-run cointegrating vectors, that the direction of Granger-causality is detected. The VECM creates an additional channel though which Granger-causality, ignored in previous tests by the standard Granger and Sims, can emerge.

Finally, the Johansen maximum likelihood method is employed to examine the response of changes in dependent variable to changes in independent variables as well as the causal relations among the variables. The inclusion of lagged vector error-correction terms (ECT) as independent explanatory variables in the estimation process will lead to the recovery all the long-run information that was lost in the original estimation process. The application of the Johansen method produces two types of relationships; the short-run dynamics and the long-run causal relationships among non-stationary variables. Granger endogeniety or otherwise of dependent variable is implied by joint statistical significance of the F-tests applied to the coefficients of the lagged explanatory variables (in first difference) and the t-tests applied to the coefficients of the lagged vector error-correction term (ECT)[4]. In other words, if the error-correction term (ECT) is statistically significant, this implies that the variable is weakly endogenous with respect to the long-run parameters. On the other hand, if the sum of the lagged explanatory variables and the ECT are not statistically significant, then there is no short-run Granger-causality among the variables, implying that the dependent variable is econometrically strongly exogenous.

To examine the Johansen and Juselius system closely, let us consider

$$X_t = \Pi_1 X_{t-1} + \ldots + \Pi_k X_{t-k} + \epsilon_t \qquad (t = 1, \ldots, T) \tag{3}$$

where X_t is a sequence of random vectors with components $(X_{1t}, \ldots, X_{pt})$. The innovations to this process, $\epsilon_1, \ldots, \epsilon_T$ are drawn from a ρ-dimensional i.i.d. Gaussian distribution with covariance Λ, and $X_{t-k+1}, \ldots X_0$ fixed. As most economic variables are nonstationary at their levels, VAR models such as (3) generally are

---

[3] See Nachega (2001) for further discussion.
[4] For more information, see Engle and Granger (1987).

estimated in first-difference form. Although this approach may produce stationary data, it paradoxically leads to a loss of some important information concerning the long-run relationship between the series and, hence, can be regarded as a source of misspecification if the series are cointegrated. To overcome this shortcoming, Johansen and Juselius (1990) suggest writing equation (3) in the following equivalent form

$$\Delta X_t = \Gamma_t \Delta X_{t-1} + \ldots + \Gamma_{k-1} \Delta X_{t-k+1} - \Pi X_{t-k} + \epsilon_t \tag{4}$$

where

$$\Gamma_i = - I + \Pi_1 + \ldots + \Pi_i \qquad (i = 1, \ldots, k-1)$$

and

$$\Pi = -(I - \Pi_1 - \ldots - \Pi_k). \tag{5}$$

The only difference between a standard first-differenced VAR model (3) and equation (4) is the term ΠX_{t-k}. It is this Π matrix that conveys information concerning the long-run relationship between the X_t variables. If X_t is nonstationary in levels while ΔX_t is stationary, the X_t is integrated of order one.

Cointegration can, therefore, be detected by examining the rank of Π matrix. The rank of a matrix is defined equal to the number of its characteristic roots that differ from zero. As such, the number of independent cointegrating vectors in the system can be determined by testing the significance of the characteristic roots of Π. It is important to note that the rank of the matrix Π is equal to the number of independent cointegrating vectors. If the rank of the matrix Π is zero, then matrix Π is null hypothesis and equation (4) reduces to the usual VAR in first differences. On the other hand, if the matrix Π is of rank n, the vector process is stationary, and for intermediate cases in which $1 < \text{rank}(\pi) < n$, there are multiple cointegrating vectors the number which can be obtained from checking the significance of the characteristic roots that differ from zero.

The short-run version of the above long-run equation can be specified as an error correction model of the form:

$$\Delta m_t = \beta_0 + \sum_{i=1}^{n} \beta_{1i} \Delta m_{t-i} + \sum_{i=1}^{n} \beta_{2i} \Delta y_{t-i} + \sum_{i=1}^{n} \beta_{3i} \Delta e_{t-i} + \sum_{i=1}^{n} \beta_{4i} \Delta r_{t-i}$$

$$+ \sum_{i=1}^{n} \beta_{5i} ECT_{t-i} + \mu_{it_t} \tag{6}$$

where Δ represent the first difference operator, ΔX_t represents changes in the log of a variable, ECT refers to error-correction terms derived from the long-run cointegration relationships using Johansen maximum likelihood technique and μ_{it}s are white-noise Gaussian random error terms where i = 1, 2, …, n. Equation (6) is the basic equation to be estimated in testing the long-run money demand function in Malaysia.

In light of Granger-causal test, an important consequence of the relationships revealed by this system of equation (6), is that either changes in the real money balances (Δm_t), real income (Δy_t), real exchange rate (Δe_t) and interest rate (ΔR_t) or any combination must be caused by ECT_{t-1} which itself is a function of changes in these variables. The theoretical assumption underlying this is that if these variables share a common trend, then current changes in the dependent variable are partly a result of the dependent variables moving into alignment with the trend value of the independent variables. For example, a change in the real money balances may be partly a result of this variable moving into alignment with trend values of real income, real exchange rate and interest rate.

For the purpose of analyzing the interrelationship among the variables and the dynamic adjustments to various disturbances in the system, equation (6) can be further transformed into its moving average representation as

$$\Lambda X = \sum_{i=o}^{\infty} B_i V_{t-i} \tag{7}$$

where the V_i are serially uncorrelated but are contemporaneously correlated with variance Ω and B_i is an n x n matrix of coefficients representing the dynamic response of each of the variances to shock V_{t-i} after i periods. Given this innovation of representation, the reaction of a given variable to future changes in n-variable system

can be accounted for. By orthogonalizing the innovations in this VAR system, we can transform these correlations by expressing Equation (7) as

$$\Delta X = \sum_{i=0}^{\infty} C_i U_{t-k} \tag{8}$$

where innovations, U_i, become uncorrelated contemporaneously with each other. While the coefficient of matrix C_i represents the response to shocks in particular variables, the variance of each element in ΔX_i is attributable to the source in elements of serially and contemporaneously uncorrelated U. It is through this orthogonalization that the variance decomposition and impulse response functions that analyze further insights about the relationships among the variables can be obtained.

By partitioning the variance of forecast error of a certain variable into proportions attributable to innovations (or shocks) in each variable in the system including its own, variance decomposition, which is termed as an out-of-sample causality tests (Masih and Masih, 1996), can provide an indication of these relativities. In other words, VDCs provide a literal breakdown of the change in the value of the variable in a given period arising from changes in the same variable in addition to others in previous periods. According to Sims (1982), a variable optimally forecast from its own lagged values will have all its forecast error variance accounted for by its own disturbances.

Another fundamental component upon which the VECM analysis is conducted is the impulse response function. Using the moving average presentation of the VAR model, each variable can be described as a function of past innovations, or unexpected shocks, of all the variables in the model. Impulse response function traces the effect of a one standard deviation shock to a variable on the time path of all the variables in the system. In other words, impulse response function measures the effect of shocks on future values of a series relative to some benchmark case. They can generally be used to investigate the persistence of shocks and other properties within the context of an empirical model where the parameters are unknown and the shocks hitting the system unknown too.

THE EMPIRICAL MODEL RESULTS

Unit Root Tests

Estimating vector error-correction mechanism (VECM) requires that the data used are stationary. Stationarity of stochastic process is an important property that ensures the constancy of means, variances and auto-variances through time. Stationarity of the time-series data is essential because regressions ignoring unit roots may produce spurious results that do not provide meaningful interpretation of economic relationships. As the results of these tests generally depend invariably on the number of lags included, lag selection must, therefore, be given a careful attention. For the importance of these tests, Campbell and Perron (1991) general-to-specific elimination procedure is employed to identify the optimal lag structure. Initially we estimate each equation with arbitrary number of lags on the dependent variable. If the lag included was significant, then the number of lags is kept otherwise, the number of lags is reduced by one while continually re-estimating the equation until a significant lagged dependent variable is found. If none of the coefficients on the lagged variables is significant, the test is run without including any number of lags. Therefore, the optimal number of lags found for theses test was 1.

Table 1 summarizes the results of the Dickey-Fuller and Phillips-Perron tests for all the variables at levels and first differences with trend and without. The null hypothesis is that the series is I(1). The test results at levels indicate that the null hypothesis of a unit root could not be rejected for all the variables. The statistical significance of absolute value of test statistics in first difference at least at five percent level indicates that the series are stationary in first differences, and hence, should be employed in causality tests and VAR/VECM in their present form.

Table 1: Unit Root Tests

Variables	ADF		PP Test	
	Constant without Trend	Constant with Trend	Constant without Trend	Constant with Trend
Levels				
y	-1.5607	-3.1462	-1.2996	-2.5221
r	-1.4429	-2.2900	-1.4201	-2.3667
e	-1.7048	-2.2996	-1.8960	-2.3854
m1	-1.0539	-2.0929	-0.8499	-2.0577
m2	-2.4975	-1.1170	-2.0400	-0.7131
First Differences				
y	-8.8244***	-8.8085***	-7.7705***	-7.8443***
r	-4.1231***	-4.0728***	-6.0659***	-6.0057***
e	-4.336***	-4.2919***	-7.8487***	-7.7868***
m1	-4.2327***	-4.3009***	-6.8116***	-6.7524***
m2	-4.8040***	-5.6336***	-6.2152***	-6.8666***

Notes: ***, ** and * indicate 1%, 5% and 10% significance level respectively. These values are provided by the Eviews package output based on Mackinon (1991). Lag truncation is 3 for all the series in Phillips-Perron Test.

Multivariate Cointegration Tests

The Johansen maximum likelihood method (Johansen, 1988 and Johansen and Juselius 1990) is applied to examine the question of cointegration among the variables. Before conducting the cointegration tests, it is necessary to determine the dynamic specification of the Johansen model. This is done by estimating the initial equations using the full data set, setting *k*, the optimal lag length, arbitrarily. The unrestricted model is then tested against a restricted version where *k* varies from 3 to 1. These tests determine the number of cointegrating vectors by testing the hypothesis that there are *r* or fewer cointegrating vectors against an alternative that the number of cointegrating vectors is greater than or equal to r. The computed test statistic is asymptotically distributed as χ^2 with n^2 (ρ_1 - ρ_0) degrees of freedom. The results of cointegration test on the specification are reported in Table 2 in which both the maximum eigenvalue and trace tests simultaneous indicate the existence of one cointegration equation, hence, rejecting the null hypothesis of zero cointegration at the 95% critical value for M1 and M2 models. Having said that, this implies that the variables in each of these models are cointegrated with at least one cointegrating equation. Based on these results, the study establishes the long-run relationship among real money demand (m1 and m2), real output, real exchange rate and interest rate in the Malaysia over the sample period.

Table 2: Results of Johansen's Test for Multivariate Cointegrating Equations

Variables: m1, y, e, r, (p = 3)					
H_0	Eigenvalue	Maximum Eigenvalue	Critical value 95%	Trace	Critical value 95%
r = 0	0.5162	34.8534*	31.46	63.8857*	62.99
r ≤ 1	0.3151	18.1694	25.54	29.0320	42.44
r ≤ 2	0.1166	5.9482	18.96	10.8625	25.32
r ≤ 3	0.0973	4.9144	12.25	4.9144	12.25
Variables: m2, y, e, r, (p = 3)					
H_0	Eigenvalue	Maximum Eigenvalue	Critical value 95%	Trace	Critical value 95%
r = 0	0.5842	29.5771*	27.07	55.8515*	47.21
r ≤ 1	0.3869	17.3642	25.54	26.2744	29.68
r ≤ 2	0.2114	8.6542	18.96	9.9102	15.41
r ≤ 3	0.1257	0.2560	12.25	0.2560	3.76

Notes: Whereas r denotes the number of cointegrating vectors, *(**) indicates rejection at the 95% (99%) critical value.

Granger-Causality Test

Testing Granger-causality among the variables is an important component of the VAR first-differenced system since the variables are cointegrated. The error-correction term ECT, derived from long-run relationship, is included in order to avoid mis-specifying the models or omitting important information. Table 3 reports the results of Granger-Causality test, based on error-correction model with uniform lag structure determined by the likelihood ratio test. The significance of the F-test and t-test statistics applied respectively to explanatory

variables (in first differences) and lagged error-correction term in m1 and m2 in addition to real output in both M1 and M2 models of money demand function imply that these variables are weakly endogenous in the VECM system, hence they bear the burden of short-run adjustment in various degrees in order to restore the system to long-run equilibrium. The F-statistic for the lag values of the independent variable in this table confirms the existence of a unidirectional short-run causal effect running from m1 to r and y, from e to r and y, from m2 to y, from e to m2, r and y. In addition, a bi-directional causality is found between r and m1. Since all the variables are cointegrated at the same level, i.e., I(1), the system can be modeled as a vector error-correction model (VECM) in the vector autoregression (VAR) system.

Table 3: Exogeneity Test Based on Vector Error-Correction Model with two lags (Uniform lag lengths)

M1 Model ($\rho = 3$)	Independent Variable				
Dependent Variable	$\Delta m1$	Δr	Δe	Δy	ECT_{t-1} t-statistics
$\Delta m1$	-	0.0006^{***}	0.3064	0.4465	-2.4020^{**}
Δr	0.0027^{***}	-	0.0268^{**}	0.0156^{**}	1.1038
Δe	0.4456	0.5820	-	0.4469	0.4247
Δy	0.0051^{***}	0.6043	0.0283^{**}	-	-2.0869^{**}

M2 Model ($\rho = 3$)	Independent Variable				
Dependent Variable	$\Delta m2$	Δr	Δe	Δy	ECT_{t-1} t-statistics
$\Delta m2$	-	0.6666	0.0008^{***}	0.8255	2.3885^{**}
Δr	0.2654	-	0.0999^{***}	0.2186	-0.5212
Δe	0.2476	0.5008	-	0.4559	0.0286
Δy	0.0281^{**}	0.9503	0.0076^{***}	-	1.7047^{*}

Notes: ***, ** and * denote significance levels at 1 percent, 5 percent and 10 percent levels respectively.

The first estimated eigenvectors would form the maximum likelihood estimate of the cointegrating vector[5], β. By normalizing on changes on the log of real broad money, we can obtain the following long-run broad money demand function:

$$m2_t = 0.0110\, e_t - 0.0456\, r_t + 1.918\, y_t$$
$$(0.1674) \quad (0.0099) \quad (0.0954)$$

Based on the signs and magnitude of the estimated coefficients, the cointegrating equation shown above can be interpreted as defining the long-run demand for real broad money in the Malaysia. In this equation, the coefficients on all the variables carry the expected correct signs as the theory predicts. In other words, the demand for real broad money in Malaysia is positively related to income and currency's depreciation rate and negatively related to the interest rate in the long run. The income elasticity of real money demand is positive and more than unity (1.92), contrary to Baumol (1952) and Tobin 1956) hypothesis. It is comparable with those of Macau (1.97), Germany (1.72), UK (1.61) and China (1.58)[6]. A test imposing unitary income elasticity was rejected: $\chi^2(1) = 163.40(0.0000)$. The rejection of unitary income elasticity implies that changes in real output have induced more than proportionate increase in real broad money in Malaysia over the sample period, implying that broad money velocity has not been constant during the period. The coefficient on semi-elasticity with respect to inflation (0.046) is significantly negative and comparable with those of China (-0.05) and Germany (0.031). Similarly, demand for real broad money in the Malaysia is positively influenced by the depreciation of domestic exchange rate, that is, a real depreciation of Ringgit Malaysia raises the demand for real broad money balances.

This restricted vector error-correction model was subjected to and has passed a number of diagnostic tests, which include serial correlation based on inspection of the autocorrelation functions of the residuals as the Lagrange Multiplier, the ARCH (4), the normality and hetroscedasticity tests. In addition, to check whether the estimation regression equations were stable throughout the sample period, the plots of CUSUM and CUSUM of square tests (Figure 3) fall inside 5% critical lines, implying that the estimated parameters of demand function are stable in Malaysia during the sample period[7].

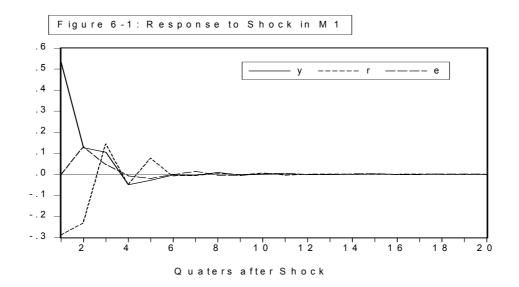
Variance Decompositions

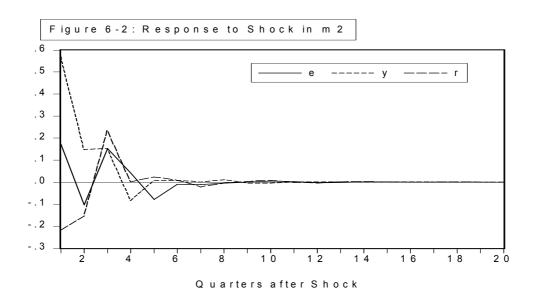
The second fundamental component upon which the standard VAR analysis is conducted is the variance decomposition function (VDCs). Further insights about the relationships among the macroeconomic variables can be obtained from analyzing variance decompositions. Variance decomposition analysis provides an indication of the dynamic properties of the system. Masih and Masih (1996) have acknowledged that, although the VECM can help to visualize the direction of causality within the sample period, it does not provide us with sufficient dynamic properties of the system. In addition, it does not measure the relative strength of the variables beyond the sample period. While the authors consider VECM analysis as a within-sample causality test, they regard the variance decompositions (VDCs) as an out-of-sample causality test. Variance decomposition practically decomposes or breaks down variation in each endogenous variable into the component shocks that can be attributed to individual endogenous variables in the VAR system and gives information about the relative importance of each random innovation to the variables in the VAR system.

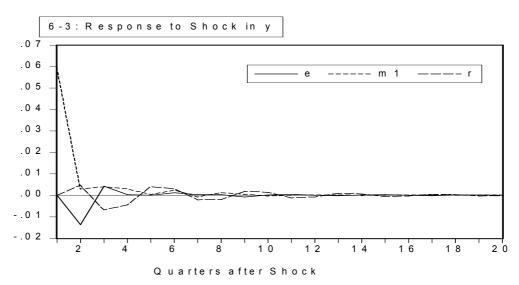
The ordering of VD is mainly based on theoretical speculation and/or some statistical properties of the system such as the correlation among the residuals and the extent of exogeneity among the variables (see Yusoff and Chin; 2000). As real exchange rate (e) and interest rate (r) appear to be the most weakly exogenous variables in the system relative to the rest of the variables, they come first in the order of real exchange (e) interest rate (e), followed by real output and real broad money. Table 5 reports the VDCs of 12-quarter forecast errors in which variance shocks to the exogenous variables are predominantly explained by their own innovations.

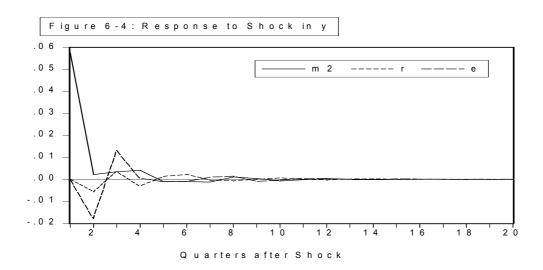
These results being consistent with those of the Granger-causality tests presented in Table 3, they indicate that m1 and m2 account for 14% and 26% of variation in the forecast error of y respectively. However, e contributes significant amounts of 32%, 14% and 36% of the variation in the forecast error of y, m1 and m2 respectively, Furthermore, r explains reasonable shares of 16% and 18% of the total volume of variation in the forecast error of y. While both m1 and m2 contribute insignificant shares of only 1% and 3% of variation in the forecast error of e, they account for similar amounts of 9% and 4% respectively in the variation of forecast error of r. Similarly, r explains a significant share of 29% and 4% of the variation in forecast error of m1 and m2 respectively. Nevertheless, y contributes very little in the total volume of variation in e, r, m1 and m2.

The results show that exchange rate is the leading cause of variation in the forecast error of real output (32% and 21% respectively) followed by money (14% and 26% respectively). Whereas r, m1 and m2 explain very insignificant portions in the variance decomposition of e, y, m1 and m2 contribute negligibly to the variance decompositions of r. Since the portion of e in the variance decomposition of m2 is the largest among the variables, this lends an important support to the conjecture of a strong causal effect running from e to m2 as confirmed by the Granger-causality test in Table 3.

Table 5: Variance Decompositions


Model M1	Percentage of forecast error variance explained by shocks in:			
Effect Upon	Δe	Δr	Δy	Δm1
Δe	87.10	2.00	9.78	1.11
Δr	11.43	72.18	7.87	8.52
Δy	32.44	16.04	37.35	14.17
Δm1	13.76	29.38	4.24	52.61


Model M2	Percentage of forecast error variance explained by shocks in:			
Effect Upon	Δe	Δr	Δy	Δm2
Δe	86.20	3.80	6.54	3.46
Δr	4.27	88.31	3.48	3.94
Δy	21.86	18.14	34.49	25.51
Δm2	35.94	2.93	1.55	59.59


Note: This variance decomposition shows the percentage of the three-year forecast error in the variable in each row to the variable at the top of the column. Since the results based on different orderings did not differ so much, so the results of the ordering (Δe, Δr, Δy, Δm2) are those presented in the above table.


Impulse Response Functions

As the impulse response functions (IRFs) are generated from a cointegrated system, a shock in any variable is expected to exert a permanent and long-lasting effect on the system, which gradually adjusts to a new equilibrium. The impulse response functions presented in Figures 6 indicate 20-quarter response of the endogenous variables to an initial shock of one standard deviation (S.D) in m1, m2 and y. Generally, the results of IRFs are consistent with the results of the VDCs that were obtained earlier. Figures 6.1-6.4 trace out the impact effect of a one standard deviation in real narrow money (Figure 6.1), real broad money (Figure 6.2) and real output (Figure 6.3 and 6-4). Specifically, Y responds massively to a one-standard-deviation shock in m1 and M2. In both cases, a shock in narrow money or broad money leads to a rise of real output, a fall of interest rate and an exchange rate depreciation. Adjustment to monetary shock in these variables dies out after a period that ranges between six to eight quarters to revert to their equilibrium values. Similarly shock to interest rates causes tremendous fall in money demand (m1 and m2) whereas exchange rate appreciates heavily.

CONCLUSIONS AND POLICY IMPLICATIONS

The objective of this paper is to estimate and test the stability of money demand function in Malaysia using the cointegration and error-correction techniques on a quarterly data on real money balances, real output as a scale variable, real exchange rate and interest rates on Government securities, from 1991:I to 2003:4. The cointegration tests indicate that both M1 and M2 are cointegrated with the specified independent variables. The estimated vector error-correction system supports a single cointegrating vector and a stable long-run real money demand function in Malaysia. The coefficients on all the variables carry correct signs and are significant (except the coefficient on real exchange rate). Khalid (1999) obtains the same result in his study of Philippines, Singapore and South Korea. This finding is consistent with evidence since interest rates in small economies are subject to regulation by policymakers or basically determined by external factors. In such cases, they are no longer a reasonable proxy for the actual costs of holding money, but just indicators of the restrictiveness of monetary policy.

The finding of persistent causality running from money (both narrow and broad) to output affirms the critical importance of money as an instrument for reviving economic activity in the short run. The Granger-causality implied by this result is compatible with Keynesian and Monetarist macroeconomic theoretical foundation that money is not neutral in the short run (Tan and Baharumshah, 1998). The findings indicate that M2 has the strongest causal effect on the real output (26% of variance decomposition compared to 14% of variance decomposition of M1). The VECM results find that demand for real money is also influenced positively and strongly by real exchange rate and real output, implying that an exchange rate (depreciation) and real GDP growth raise the demand for real money balances people would like to hold.

Finally, the finding of a single stable long-run money demand function has important policy implication for Malaysia in that if the central bank wants to control the total liquidity in the economy, it can do so by identifying appropriate medium-term growth targets for money supply and manipulate interest rates and reserve money. While the lack of sufficient quarter data on some of the series has been an obstacle to this study, nevertheless, these findings are consistent with a number of studies. For example, Hayo (2000) finds that while M1 money demand function was unstable, M2 money demand function displays long-run stability in Austria. Furthermore**,** Koǧar (1995) finds that M1 and M2 demand functions in Israel and Turkey are stable. Likewise Nachega (2001) finds that the demand for M2 in Cameroon is stable. As Tan and Baharumshah (1999) have found that M1 and M3 appear to have a significant effect on output and prices, a further study is needed to provide convincing evidence supporting this finding and the reason which might have prompted the Central bank to switch from M2 to M3 as a primary monetary target.

APPENDIX

Definitions and sources of variables

Unless otherwise indicated, the data series are drawn mainly from the IMF *International Finance Statistics (IFS),* with exception of interest rates, all the series are in natural logarithms.

p: consumer price index (2000 = 100).

e: is the logarithm of the Malaysian ringgit per US dollar exchange rate. Hence, Δe is the depreciation rate.

m: logarithm of real money (narrow and broad money).

y: logarithm of real GDP.

i: interest rate on Government securities (three-month treasury bill).

DUM: dummy taking value of one between 1991:1 and 1998:2 when the ringgit was floating and zero between 1998:3 to 2003:4 when it was pegged to the US dollar.

The Instability of the Long Run Money Demand Function: An I(2) Interpretations

ABSTRACT

The paper attempts to provide an empirical analysis to detect the existence of long run stable money demand function in Malaysia. Using Divisia index of money, the analysis is performed within the newly developed cointegrated I(2) VAR framework proposed by Rahbek *et al*. (1999), offering some insights about the dynamic links between stock money, prices, economic activity and interest rates. The empirical findings conclude that the demand for money in Malaysia is stable.

INTRODUCTION

One of the most enduring analytical devices in macroeconomics has been the aggregate money demand function. A stable demand for money function plays an integral role in the formulation of successful monetary policy. From a monetarist point of view, the effectiveness of the monetary policy is subject to the condition that the supply of money grew in line with the demand for money – at least, the demand for money function should be stable. The existence of a well define and stable money demand function is thus a primacy for a reliable transmission of the impact of changes in the money supply to aggregate spending (Hossain and Chowdhury, 1996).

As the theoretical and empirical appeal of monetarism grew through the 1970s, most countries, including Malaysia, devoted more attention to movements in the monetary aggregates. Given that price stability was the ultimate objective of monetary policy, Malaysia has adopted the practice of announcing targets for monetary growth in order to tie down inflationary expectations.

However, subsequent development in the economy and the financial innovation and regulatory changes during the early 1990s has severely distorted the monetary outcome. This has contributed to generating doubts about the usefulness of monetary aggregates in the conduct of monetary policy. Indeed, the Bank Negara Malaysia has shifted its focus from monetary targeting to interest rates targeting.

While this decision was a matter of judgment at the time, reflecting the findings of instability in money demand function, the literature on the use of money has evolved in different ways. A first strand of the literature has looked at ways of improving money demand models, this including focusing on whether an incorrect definitions of money could be the reasons why the demand for money function had become unstable.

There has been a growing literature on the measurement issue concerns the definition of money. The way money is defined is crucial in setting the boundary of monetary policy: as Cagan (1991) put it: "the definition of money for policy purposes depend on two considerations: the ability of the authorities to control the quantity, and the empirical stability of a function describing the demand for it".

In a sequel of papers, Barnett (1980, 1987, and 1995) argued that simple sum aggregation of money, which is usually employed by central banks, can only useful as accounting identities, since they cannot approximate the service flow that money provides: they cannot approximate the economic good that one would call money. Barnett proposed the use of Divisia monetary indexes as an alternative to the simple sum aggregates: Divisia index possess some appealing properties that not only performed well relative to the desirable properties of the statistical index numbers, but also provide high quality approximations to values of the economic quantity and price aggregates of aggregation theory.

Indeed, empirical evidence of the superiority of the divisia index in Barnett et al (1984), Belongia and Chalfant (1989), Chrystal and MacDonald (1994) as well as Konstaninou (2002) give rise to the question whether the instability of the conventional standard money demand function is attributed to mis-measurement of the money and the potential 'correction' of such mis-measurement. Chrystal and MacDonald (1994) have observed the following regarding "the problems with tests of money in the economy in recent years...may be more due to bad measurement rather than instability on the link between the true money and the economy…rather than a problem associated with the Lucas Critique, it could instead be a problem stemming from the 'Barnett Critique.'" As a matter of fact, this Barnett Critique issues have been used to cast doubt upon many widely hold views in monetary economics, as recently emphasized by Barnett, Fisher, and Serletis (1992), Belongia (1993), and Chrystal and MacDonald (1994). Based upon this rapidly growing line of research, Chrystal and MacDonald (1994) conclude---in our opinion correctly---that: "Rejections of the role of money based upon flawed money measures are themselves easy to reject."

The second strand of research has turned into the investigation of the usefulness of money as an indicator for the conduct of monetary policy. There have been recent developments in the time series analysis, which seek to uncover *long-run* relationships between the money stock, economic activity and interest rates, utilizing the cointegration analysis. Accordingly, cointegration is a necessary condition for a money demand equation to be stable in the long run (Melnick, 1995; Ericsson and Sharma, 1996): although there may be short run deviations in the presumed relationship between money and income, there may be some underlying economic relationship to which two series revert over time. If money and income do in fact move together over time, and if reversion to the joint long run path is possible, then economic analysts are more likely to regard monetary aggregates as containing useful economic information.

The determinants of the long run money demand function have been the subject of a large number of studies using a variety of methods and variables selection. One difficulty often present in the empirical analysis of economic time series is the determination of the order of integratedness of a series. Theoretically, a process is either I(0) or I(1) or I(2). In practice many variables, or combination of variables are borderline case such that distinguishing between a strongly autoregressive I(0) or an I(1) process are far from easy (interest rate is a typical example) or between a strongly autoregressive I(1) or I(2) process (nominal prices are typical example). Allowing for local linear trends in the data and, even worse, in the cointegration space, increase the ambiguity more.

The usual assumption underlying the existing literature, which is also been documented by univariate non-stationary test, in most of the cases, is that nominal money and prices are better described statistically as being integrated of order two, denoted as I(2) (Johansen, 1992; Haldrup, 1994; Juselius, 1994 and Paruolo, 1996)[1]. As a remedy for reducing the order of integration while preserving cointegration relationships, guided by theoretical consideration, nominal-to-real transformations are routinely used - deflating the logarithm of nominal monetary aggregates, with the logarithm of the price index, p (i.e. imposing long run price homogeneity) in the form that real money (m_t-p_t), defined as an I(1) process, has become a common practice in the literature[2].

In the literature, there is general agreement that the demand for money balance in the long run is demand for real balance, (m_t-p_t) and is a function of a scale variable (as a measure of economic activity) such as GDP and a set of opportunity cost variables (to indicate the foregone earnings by not holding assets, which are alternative to money). This cost may be also reflected in the inflation rate. These variables, are then treated empirically as first-order integrated processes. By implication, nominal money, m_t, and the price level, p_t, are I(2), sharing a common stochastic trend and thus cointegrating to I(1).

Modeling real money and inflation, instead of money and prices, with the underlying implicit assumption is that the system has been successfully transformed from I(2) to I(1) model, forms the starting point in most empirical studies of money demand relationships in the existing literature. However, treating the validity of the transformation by assumption runs a significant risk in term of inference on number and structure of cointegrating relations. Kongsted (1999) demonstrated that, under certain condition, a nominal-to-real transformation that fails in terms of I(2)-to-I(1) cointegration can leave the transformed variables integrated of order two, and, consequently, I(1) inference and interpretation will not valid. In facts, Fiess and MacDonald (2001) pointed out that the widely noted instability of money demand functions go hand-in-hand with a nominal-to-real transformation that is unsuccessful in achieving an I(2)-to-I(1) reduction.

Using the newly developed I(2) cointegration which allow for trend stationary component proposed by Rahbek *et.al* (1999), this study focus on the money demand for Malaysia by looking at the Divisia index of money

---

[1] See Haldrup (1998) for a recent survey on the econometric analysis of I(2) variables.
[2] Such a nominal-to-real transformation, rest implicitly upon the assumptions, that money and prices are both I(2), but share one common I(2) trend, and this common trend can be expressed as an I(1) relationship which conforms in vector form to (1, -1), i.e. m-p.

instead of the conventional measure of monetary aggregates. The cointegration I(2) model allows tests of cointegration between nominal variables which appear relevant to cater for I(2) component as well as for linear trend in the multivariate framework. It is generally believe that the far-reaching changes in the Malaysia's economy and the financial system have caused considerable instability of the money demand function for Malaysia. Such phenomena can appear as ongoing changes in the opportunity cost of the money holding which can be modeled as a linear trend (See Hendry and Ericsson, 1991; Dekle and Pradhan, 1999).

Beside this, the I(2) cointegration analysis can be serve as additional misspecification test for testing for I(2)ness of the I(1) model (Rahbek *et al*, 1999). If $m_t - p_t$ is CI(2,1) in the sense of Engle and Granger (1987), then inference in I(1) model using a real balances and the growth rate of one of the nominal variables is valid (see, Kongsted, 1999). But, if $m_t - p_t$ is still an I(2) variable, then by assuming a priori that m_t-p_t is an I(1) variable, this will lead to invalid inferences since I(1) model would not appropriate for the analysis. Any relation between m_t-p_t and the rest of the variables in the system would be spurious.

Accordingly, the present analysis proceeds in two stages. Firstly, to detect the number of I(2) and I(1) trends in the data, as well as the cointegration relations which include linear trend, each of the money demand function with different definition are analyzed in the I(2) cointegration space. Next, to see whether the nominal-to-real transformation has successfully transformed the system from I(2) to I(1) system while maintaining the cointegration relationship without the loss of the long run information,
An analysis of I(2) space of the real money and real aggregate demand functions are tested. The paper is organized as follows. Section 2 presents the framework of estimating the long run money demand function as well as the data utilized in the present study. Section 3 contains a brief discussion on the I(2) cointegration. Section 4 present the empirical results and sections 5 end up with conclusion.

THE LONG RUN MONEY DEMAND ESTIMATION

The standard theory of the demand for money generally distinguished three motives for holding money: the transactions motive, the precautionary motives and the speculative motive. All of these lead to a simple Keynesian-type demand for money function

$$M = f(P,Y,C)$$

Where nominal money being positively related to the price level (p) and the real income (Y) and negatively related to the opportunity cost (c) of holding money.

In equilibrium

$$Ms =Md$$

In the money demand function literature, there is overwhelming agreement that in the long run the money balances depend on a scale variable such as the real income and at least one interest rate. The former variable reflects the fact that money is used for transaction purpose and the latter represent the opportunity cost of holding money.

Empirically, in this study, the empirical analysis will be performed for a four-dimensional vector,

$$z_t^{'} = [m, y, p, i]_t, \quad t=1981:03, \dots,2003:04.$$

Where m is the divisia monetary aggregate index (further detail on the construction of the Malaysia monetary services index are provided in Habubullah, 1998), y is the income measured by real GDP; Price level measured by consumer price index, and the interest rates is the 7 day inter-bank interest rates. All variable are in logarithms with the exception of the interest rates.

ESTIMATION METHOD

Consider the general VAR model with Gaussian error in p-dimensions

$$z_t = \eta + \sum_{i=1}^{p} \Pi z_{t-i} + \varepsilon_t \tag{1}$$

where η is a (nx1) vector of deterministic variables, and ε is a (n x 1) vector of white noise disturbances and mean zero. The purpose of the cointegration analysis is to distinguish between stationary by linear combinations and by differencing. Therefore, the model can be reformulated into the vector error correction (VECM) as,

$$\Delta z_t = \eta + \sum \Gamma_i \Delta z_{t-i} - \Pi z_{t-i} + \varepsilon_t \tag{2}$$

where Δ denotes the first difference operator, Γ_i is a (n x n) coefficient matrix (equal to $-\sum_{j=i+1}^{p} \Pi_j$), Π is a (n x n) matrix (equal to $-\sum_{j=i+1}^{p} \Pi_j - I$), whose rank determines the number of cointegrating vectors.

The hypothesis of cointegration is formulated as a reduced rank of the Π matrix

$$H_1(r) : \Pi = \alpha\beta'$$

where α and β are p x r matrices of full rank.

I(1) cointegration occurs when Π is of reduced rank, $r < p$ in the reduced rank case, Π can be factorized into Π (= $\alpha\beta'$) where α and β are p x r matrices and α denotes the adjustment coefficients and β is the cointegrating vectors. The cointegrating vector β have the property that $\beta'z_t$ is stationary, even though that z_t itself is not stationary. Thus, within the I(1) framework , the hypothesis of I(1) cointegration is formulated as the reduced rank $\Pi = \alpha\beta'$ and the full rank of $\alpha\perp'\Gamma\beta\perp$ and $\alpha\perp$ and $\beta\perp$ are p x (p − r) matrices orthogonal to α and β. Therefore, it can be distinguish between r cointegrating I(0) relation and p-r non-cointegrating I(1) relations.

The I(2) model which allows the p-dimensional vector of time series, z_t, to be linearly trending and have some or all the components integrated of order two may be understood by referring to equation (3):

$$\Delta^2 z_t = \eta - \Pi z_{t-1} - \Gamma \Delta z_{t-1} + \sum_{i=1}^{p-2} \phi_i \Delta^2 z_{t-i} + \varepsilon_t \tag{3}$$

where $\quad \Gamma = I - \sum_{i=1}^{p-1} \Gamma_i$ and $\phi_i = -\sum_{j=i+1}^{p-2} \Gamma_i$, I = 1,…, p-2.

The I(2)framework relax the assumption that $\alpha\perp'\Gamma\beta\perp$ is a full rank and postulates that not only must $\alpha'\beta$ be of reduced rank, but also $\alpha\perp'\Gamma\beta\perp$, which now becomes (p-r) x (p-r) and is of reduced rank s1. $\alpha\perp'\Gamma\beta\perp$ therefore can be expressed as $\alpha\perp'\Gamma\beta\perp = \xi\eta'$, where ξ and η are matrices of order (p x r) x s_1 with $s_1 < $ p-r.

The hypothesis H1(r) implies that the process Δz_t is stationary, z_t is nonstationary, but $\beta'z_t$ is stationary (see Johansen, 1991). Thus, the relations $\beta'z_t$ can be interpreted as stationary relations among nonstationary variables.

EMPIRICAL RESULTS

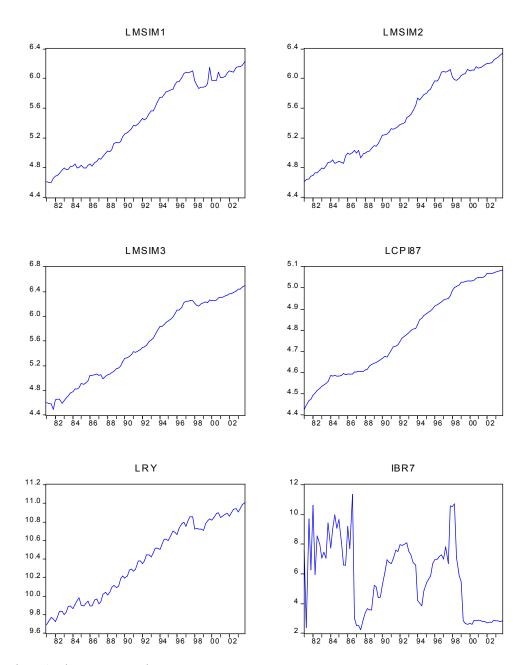
A visual plot of the data is usually the first step in the analysis of any time series data. Figure 1 highlights a number of features of the data. The nominal variables, namely the divisia money and the price level, are clearly nonstationary. In similar pattern the real GDP showing upward trend pattern. The interest rate does not appear stationary but it seems to have no significant deterministic trend.


Figure 1: The Data In Levels

Juselius (1996) argued that there exist ample empirical evidence that both the measures of prices level and nominal money stocks are best described as I(2) integrated variables. Not surprisingly, the empirical results of the augmented Dickey-Fuller unit root test reported in Table 1 provide some initial evidence in favor of such assumption. The remaining series, namely, real GDP and the interest rates, are at most integrated at order one.

Table 1: Univariate Unit Root Tests

	Level	First difference	Second Difference
	Constant with Trend	Constant without Trend	Constant without Trend
LMSIM1	-1.9217 (9)	-2.4764 (8)	-6.1180 (7)***
LMSIM2	-2.7561 (12)	-1.8780 (11)	-5.1226 (10)***
LMSIM3	-1.6146 (8)	-2.3875 (12)	-3.2206 (11)**
LRGDP	-1.9344 (4)	-3.3593 (3)**	-10.4452 (2)***
LCPI	-1.5213 (5)	-4.3123 (4)***	-5.2132 (10)***
IBR7	-3.1092 (2)	-17.1147 (0)***	-7.2346 (4)***

Note: MSIM1, MSIM2 and MISM2 denotes, divisia money M1, M2 and M3, RGDP stands for real GDP, CPI and IBR7 refer to consumer price index and 7 days interbank rate, respectively. All variable are in logarithms with the exception of the interest rates.

To proceed with the Rahbek *et al* (1998) I(2) cointegration analysis, the first step is to determined the lag length, k, of the VAR model. Using general-to-specific reduction of the VAR model, the AIC and the reduction process indicated that a lag order of 5 was adequate for the models in the present study. The results for the I(2) analysis on the money demand model with difference measures of monetary services index are presented in Table 2 to 4.

Table 2: An I(2) Analysis of [LMSIM1, LCPI, LRGDP, IBR7] 1982:03 to 2003:04 VAR (5)

p-r	r	$Q(s_1,r)$				$Q(R)$

					(17.57)	(10.63)
					19.87	12.49
p-r-s		4	3	2	1	0

Note: Numbers in parenthesis (Italic) are 90 (95%) quantiles from table 8 in Jorgensen, Kongsted and Rahbek (1999)

For inference on the cointegration ranks, the test statistics $S_{r,s}$ are compared to the 95 percent quartiles of the asymptotic distribution. To begin with, the I(2) analysis of the money demand function for nominal divisia money M1(LMSIM1), the price level (LCPI), real GDP (RGDP) and short tem interbank rate (IBR7) is performed and reported in Table 2. Reading from the top left corner, moving towards the right to the end of the first row, the most restricted model ($r = 0$, $s_1 = 0$, $s_2 = 4$) can be safely rejected. In all, the test statistics firmly reject $r = 0$. The first non-rejection case will be the hypothesis of one polynomial cointegrating relationship ($r = 1$) with one I(1) trend ($s_1 = 2$) and two ($s_2 = p – r - s_1 = 2$) I(2) trends in the system. From the results of Johansen (1992b) and Haldrup (1994), the natural candidates for I(2) variables are most likely be m_t and p_t. The likelihood ratio test for no linear trend in the polynomial cointegrating relationship yields a test statistics of 15.89 with p-values of 0.000. Thus, there is clearly a role for linear trend in the multi-cointegrating relations.

p-r-s		4	3	2	1	0

Akin to the case of MSIM1, similar conclusion can be drawn for the money demand model with LMSIM2 and LMSIM3. As reported in Table 3, applying the rank test procedure of Rahbek *et al.* (1999) on the vector of [msim2, cpi, rgdp, r] suggested that the models having r = 0 can be firmly rejected. A non-rejection occurs for the case (r,s) = (1,2). This suggests that the model comprises 2 common I(1) and two common I(2) stochastic trends with the existence of one cointegrating vector. The likelihood ratio test of 25.95[0.000] indicated that the linear trend the cointegration space is significant.

With respect to the LMSIM3 model, it can be observed that the hypothesis of no cointegration (r =0) can be rejected. The testing procedure stops, when the test statistics $S_{r,s}$ of 52.40 reveal that the hypothesis of (r,s) =(1,2) cannot be rejected. The likelihood ratio test of no linear trend of 14.03 [p-value=0.000], suggesting the presence of the deterministic trend in the polynomials cointegration relationship.

Since the I(1) model are still more developed compared to the I(2) model, we are interest in whether deflating the logarithm of nominal money by the logarithm of the price index, or, in other word, by imposing price homogeneity, represent a nominal-to-real transformation that result in a successful I(2)-to-I(1) model without the loss of generality. When modeling real money and inflation, instead of nominal money and price, the implicit assumption is that, according to Fiess and MacDonald (2001)

'…(1) that money and prices are both I(2), but share one common I(2) trend
  (2) that this common I(2) trend can be expressed as an I(1) relationship which conforms in vector form to (1, -1), i.e. m-p…'

In such as case, imposing price homogeneity with a successful I(2)-to-I(1) model, one should arrive with the similar conclusions with using an I(2) cointegration analysis. By pre-imposing real money, (m-p), if it does not remove all I(2) component s from the system, then moving to an I(1) model could lead to questionable statistical inference. To ensured that all I(2) components have been removed from the transformed system, an I(2) test are performed on the vector [(m-p), Δp, yr, r], reported in Table 5 - 7.

Table 5: An I(2) Analysis of [LMSIM1-LCPI, ΔLCPI, LRGDP, IBR7] 1982:03 TO 2003:04 VAR (5)

p-r	r	$Q(s_1,r)$				Q(R)

p-r-s		4	3	2	1	0

The joint rank statistics, S $_{r,s}$, 47.79, pointing to one I(2) trend and one cointegrating relationship exists in the vector of [LMSIM1-LCPI, ΔLCPI, LRGDP, IBR7] reported in Table 5. Evidence of I(2)'ness in the system would suggest a failure in achieving an I(2)-to-I(1) cointegration in such a case.

Table 6: An I(2) Analysis of [LMSIM2-LCPI, ΔLCPI, LRGDP, IBR7] 1982:03 to 2003:04 VAR (5)

				(44.52)	(31.61)	(22.98)
				47.60	34.36	25.43
1	3				15.99	4.20
					(17.57)	(10.63)
					19.87	12.49
p-r-s		4	3	2	1	0

As presented in Table 7, pre-imposing price homogeneity does not remove the I(2) components in the (LMISM3-LCPI) money demand function. An I(2) analysis of RMSIM3, inflation, real GDP and interest rates revels that there exist 2 I(2) trend, one I(1) trend with one cointegrating relationship.

AN I(1) ANALYSIS OF (LMSIM2 - LCPI) DEMAND FUNCTION

Since pre-imposing the price homogeneity remove all the I(2)'ness in the (LMSIM2 – LCPI) money demand function, the standard I(1) cointegration analysis is performed on [LMSIM2-LCPI, ΔLCPI, LRGDP, IBR7]]. To attain a model with the appropriate lag length, the cointegration test is repeated by sequentially reducing one lag at a time (beginning with a maximum of 7 orders VAR) until the length reaches one. The top panel of the Table 8 reports the Schwarz (SC) and Hanna-Quinn (HQ) information criteria for the selection of lag-length (k) and various diagnostic statistics on the system residuals: Lagrange–Multiplier tests for first-(LM(1)), fourth-(LM4)),the normality test of normality which based on a multivariate version of the univariate Shenton-Bowman test.

Statistically, the VAR(5) appears reasonably well specified over the estimation sample, although some normality is reveled by the normality test of normality which based on a multivariate version of the univariate Shenton-Bowman test. Excess kurtosis in the residuals of the equations for short tem rate, due to the presence of some outliers at the beginning of the estimation period, appears primary responsible for this finding.

Table 8: Summary Of Results From The Application Of The Johansen Procedure

Information criteria	SC	HQ	
K=1	-22.3951	-22.7929	
K=2	-22.2735	-22.9412	
K=3	-22.3744	-22.3157	
K=4	-22.2220	-23.4410	
K=5	-22.3904	-23.8910	
K=6	-21.8408	-23.6273	
Test diagnostics (k=5)	LM(1)	LM(4)	Normality
Multivariate statistics	18.017	17.937	30.024
	[0.32]	[0.33]	[0.000]***
Univariate statistics	Kurtosis	ARCH(5)	Normality
LMSIM2-LCPI	4.2365	8.529	8.438
DLCPI	3.5216	6.767	0.865
LRGDP	3.6872	6.654	1.356
IBR7	5.5970	8.459	32.802

Note: LM(1) and LM(4) denotes LM test for vector (series) first and fourth-order autocorrelation and the test of normality is based on a multivariate version of the univariate Shenton-Bowman (1977) test. For univariate statistics, ARCH is Engle' test against conditional heteroskedaticity of order 6 in the residuals, and normality refer to the modified version of the Shenton-Bowman test for normality of the individual residual series (see Doornik and Hansen, 1994)

Table 9 shows the results for the maximum and the trace test. The trace statistic rejects the null hypothesis of no cointegration in favour of at least one cointegrating relationship while the maximum eigenvalue suggest that cointegration rank is equal to two. As this remains the case, given that the trace statistics is more robust to the non-normality problem encountered in the data, the cointegrating rank is set equal one[3].

Table 9: An I(1) Analysis of [LMSIM2-LCPI, ΔLCPI, LRGDP, IBR7] 1982:03 to 2003:04 VAR (5)

Eigenv.	H0: r	p-r	L-max	L-max 95	Trace	Trace 95

---

[3] See Cheung and Lai (1993).

Table 10 reports the tests for long run exclusion, stationarity and weakly exogeneity of each variable. Conditional on the choice of cointegrating rank r = 1, none of the variables can be considered stationary.[4] The remaining test on the systems indicates that this is not the final representation. In particular, the exclusion test shows that the short term rate can be excluded from the long run relationship and the weakly exogeneity test indicated that (LMSIM2-LCPI) and IBR are weakly exogenous. This suggest that the rmsim2 might be preferable as a monetary target as it seems to be weakly exogenous for the long run parameter (Juselius and Hargreaves,1992).

CONCLUSION

The paper attempts to provide an empirical analysis to detect the existence of long run stable money demand function in Malaysia. Using Divisia index of money, the analysis is performed within the newly developed cointegrated I(2) VAR framework proposed by Rahbek *et al*. (1999), offering some insights about the dynamic links between money, prices, economic activity and interest rates. The empirical findings show that there is at least one I(2) trend in the systems of variables employed. In such a case, the resulting I(2) cointegration model reveal that cointegration relationships holds in the model of nominal divisia M1, M2 and M3.

Since the I(2) model is not as developed as the I(1) cointegration test, we are interested in whether data transformation allow one to move to the I(1) model without the loss of generality. In other words, whether a nominal-to-real-transformation success in terms of I(2)-to-I(1) cointegration can leave the transformed variables integrated of order one (i.e. by removing all the I(2)ness in the system), and consequently, I(1) inference and interpretation will be valid.

The empirical results further demonstrated that I(1) inference and interpretation of real transformed system need not to be valid even though the system is transformed according to the theoretical considerations that are satisfied by the polynomial cointegration relationships. In particular, while imposing long run price homogeneity does not remove the I(2) components in a model of divisia money M1 and M3 demand functions, the nominal-to-real transformation model does performed well for the case of divisia money demand M2.

The Us and Japanese Interest Rates Volatility and Money Demand in Malaysia

ABSTRACT

The US and Japan are the two major trading countries for Malaysia. In this paper we examine the effect of the US and Japanese interest rates uncertainty on the money demand in Malaysia. The conditional variance estimated from GARCH(1,1) model in the study represents the US and Japanese interest rates volatility. On the basis of the Johansen multivariate cointegration test we investigate the long-run relationship between real money demand in Malaysia and the volatility of the US interest rate, and between real money demand in Malaysia and the volatility of the Japanese interest rate. We observe that the US and Japanese interest rates do have significant influence in determining the demand for money in Malaysia. Nevertheless, the opportunity cost of holding money remains to impose larger effect on the money demand function.

INTRODUCTION AND LITERATURE REVIEW

This paper presents an empirical analysis of the effect of the US and Japanese interest rates volatility on the stability of money demand in Malaysia. A major behavioral relationship in monetary theory and policy is the demand for money. The money demand function has been subjected to extensive theoretical and empirical research because of its crucial importance as a fundamental building block in macroeconomic theory and as a critical component in the formulation of monetary policy. The effectiveness of monetary policy depends on the stability of the money demand equation as such changes in the money supply will have predictable impacts on real variables. The evolution in the financial system as a result of technological changes and financial innovations are believed to be the factors attributed to the instability of the demand for money (Ford, Peng, and Mullineux (1992), Ford and Mullineux (1996)).

The current empirical research on the effect of interest rate volatility on the money demand function is rather limited and presently only confined to U.S. data. Given the fact that there may be important effects on monetary policy caused by interest rate volatility, research in this area is rather important.

In his study on intertemporal paths for household's consumption and portfolio allocation of wealth, Marquis (1989) concludes that the volatility of the interest rate could alter the optimality of the household's consumption and portfolio decision. Consequently, changes in the portfolio holding will have an affect on household's demand for money. However, in a stochastic environment these shocks are quickly offset by the subsequent shocks that attenuate the household's consumption and portfolio allocation response. On the effect of interest rate volatility on the partial equilibrium household demand for money, Marquis (1989) demonstrates that the volatility of the short-term interest rate does not necessarily imply an increase in money demand. Greater short-term or long-term interest volatility according to him has an ambiguous net effect on the household's quantity of money demanded due to cross-correlations of interest rates with each other and between interest rates and inflation rates. Garner (1990) argues that the economic experience in the U.S. in the early 1980's is difficult to interpret because of unusual circumstances that could obscure an interest rate volatility effect. He added that deposit deregulation and technological change may have altered permanently the behavior of money demand, and relative volatility measures may not represent accurately all movements of interest rate and inflation rate uncertainty. Thus, an empirical study on interest rate volatility in the U.S. using a sample period of 1959-1984 provides little evidence to support the hypothesis that interest rate volatility raises demand for money. However, he found interest rate variability to have a negative impact upon money demand over the period 1959 to 1973 which he argues might be due to inflation uncertainty dominating the relatively constant real interest rate. Garner (1990) concludes that interest rate volatility may affect real economic variables through such channels as bond risk premiums and direct effects on business investment spending. As such, a significant presence of interest rate volatility in the money demand function could have important effects on economic performance and monetary policy.

Subsequently, Arize and Darrat (1994) in their empirical study used U.S. quarterly data of 1963Q1-1991Q4 and included money-growth volatility and interest rate volatility as additional regressors in the U.S. M2 demand equation. Their study shows that there is little evidence that interest rate variability has significant influence on

M2 demand for the U.S. Payne (1995) applies a Granger-causality framework to investigate the effect of the variability of the interest rate on the velocity of money. He finds evidence that variability in the short-term interest rate and in some cases the long-term interest rate affects velocity. He concludes that the variability of interest rate measures Granger-cause velocity.

Choudhry (1999) explains that volatility in the nominal interest rate is due to the volatility in the real interest rate or in the expected rate of inflation. This explanation coincides with the suggestion by Garner (1990) that much of the actual nominal interest rate volatility may be due to inflation rate volatility which reflects the inverse relationship between money demand and interest rate volatility. Choudhry (1999) indicates that both interest rate and inflation rate volatility play a significant role in the M1 demand function in the U.S., although the size and direction of the effect is not identical in every relationship. He concludes that interest rate volatility imposes a significant effect on real M1 demand if the long-term interest rate is included in the money demand function. Furthermore, in an increasingly interdependent global economy among countries, monetary developments in one country could affect both the supply and demand for money in other countries. One implication of the increased interdependence is that the aggregate demand for money in a country could be sensitive to foreign monetary developments, such as a change in foreign interest rates (Bahmani-Oskooee, 1991). A monetary policy which is formulated to counteract foreign monetary and financial developments will require knowledge of the sensitivity of the money supply to those events as well as knowledge of the response to the demand for money.

The literature on money demand is quite abundant but there are not many studies that link the US and Japanese interest rates volatility on the stability of money demand for developing countries. Note that U.S. and Japan are the two major trading partners of many emerging economies including Malaysia. Increasing globalization of the financial system and interdependent of global economy among countries today may have significant implication towards formulating the effective monetary policy in Malaysia. Thus, it is imperative to understand how this external factors particularly the volatility of the US and Japanese interest rates, the two major trading partners for Malaysia, could influence the money demand function of this country. This study is important in its contribution to a better understanding on the effect of foreign interest rates volatility in money demand function particularly for a small open economy such as Malaysia.

The remainder of this paper is organized as follows. Section II discusses on the model to be estimated and methodological issues on volatility of the interest rates. Data used in this study also discussed in section II. The theoretical framework that underpins the empirical analysis and the discussion on the results of the analysis are presented in Section III. Finally, Section IV presents a brief summary of the major results and conclusions.

DATA AND METHODOLOGY

The empirical work outlined in subsequent sections employs quarterly data. Series used in this study are the M1, M2, quasi money, consumption, base lending rate, interest rates (such as fixed deposits rates, savings rates, lending rates, money market rates, treasury bills rates, and rates for government securities) and consumer price index. These data are extracted from various issues of *Bank Negara Quarterly Statistical Bulletin*. In addtion, the US 3-month treasury bill rate and Japan callmoney are obtained from *International Financial Statistics* of the International Monetary Fund database CD-ROM. Other data series such as claims on the banking sector, claims on government, net foreign assets, claims of the monetary authorities and the banking sector on the private sector are also obtained from *International Financial Statistics* of the International Monetary Fund database CD-ROM. The period of the data for this study is 1976Q1 to 2001Q4.

Model

For the purpose of this study, the estimated model is based on the general functional form for the money demand function which is specified as follows:

$$M / P = \alpha y^{\beta} R^{\theta} \qquad (1)$$

Taking logarithms:

$$\ln(M / P)_t = \ln \alpha + \beta \ln(Y / P)_t + \theta \ln R_t + u_t \qquad (2)$$

where *M* is the quantity of money balances i.e. *M2*, *P* is the general price level, *Y* is income, *R* is the nominal interest rate, *α, β, θ* are parameters, *t* is the time period, and *u* is a random error term. In this study, the financial

wealth is also included in the model. This variable is considered relevant because with the development of the financial sector in Malaysia more financial products are made available to the public as alternative to money. Fase and Winder (1996a) point out that the role of wealth is unarticulated and almost ignored in empirical research on money demand. Since then, the inclusion of income or wealth or both in the money demand function has remained an issue. Following Fase and Winder (1996b) the net financial wealth of the non-monetary private sector is used as the relevant wealth variable. This is defined as the difference between total assets -the sum of M1, quasi money, claims on the banking sector and on the government and net foreign assets - and the claims of the monetary authorities and the banking sector on the private sector. The estimated final model is determined as follows:

$$\ln(M/P)_t = \ln\alpha + \beta_1\ln(C/P)_t + \beta_2\ln R_t + \beta_3\ln(FW/P)_t + \beta\ln V_t + u_t \tag{3}$$

where C represents the scale variable. The real consumption is used instead of income as the scale variable. FW is the financial wealth, and V is the variability of the US and Japanese interest rates. Finally, R is the opportunity cost of holding money that is the user cost[1]. This user cost is derived by Barnett (1978) and given as:

$$R_{it} = P_t\frac{(r_t^b - r_{it})}{(1 + r_t^b)} \tag{4}$$

where

R_{it} represents the user cost of asset i at time t,
P_t represents the consumer price index,
r_t^b represents the benchmark rate,
r_{it} represents the rate of return from the ith monetary asset at time t.

In this study i is the Malaysian 3-month treasury bill rate. In theory, the benchmark rate of return, r_t^b is defined as the maximum expected holding period yield of a pure store-of-value asset. The benchmark asset is specifically assumed to provide no liquidity or other monetary services and is held solely to transfer wealth intertemporally. The predominant approach to measuring the benchmark rate is to view r_t^b as the maximum-available holding-period yield at each point in time. In this context, it is possible that different assets will occupy the role of the benchmark asset at different moments in time (Belongia, 2000). An arbitrary constant is added to r_t^b so that user costs are always positive. According to Mullineux (1996), the pragmatic solution to the benchmark problem is usually to include a (medium to long-term) local authority or government bond rate set along with the own rates of the monetary component assets and then to form the benchmark series by taking the highest rate in the set period by period. This will ensure that $R_i \geq 0$. A constant is added to avoid zero weight in the highest-yielding monetary component in a particular period.

In the case of Malaysia, where data on corporate bonds is not readily available the other viable alternative assets i.e. the treasury bills and the government securities are included to compute benchmark rate[2]. Thus, the maximum among own rates at each point in time is chosen as the benchmark rate, i.e.

$$R_t = \max\{RDD_t, RSVD_t, RFXD_t, RNCD_t RREPOS_t, YGS_{it}\} \tag{5}$$

where RDD is the own rate of return on demand deposits, RSVD is the own rate of return on savings deposits, RFXD is the own rate of return on fixed deposits, RNCD is the own rate of return on negotiable certificates of deposit, and RREPOS is the own rate of return on repurchase agreements, and YGS represents the return on the treasury bills and yield on government securities.

Interest rate volatility

The volatility of the interest rate in this study is represented as the conditional variance of *GARCH (p,q)* model. For modeling changing volatility under deviations from linearity, Engle (1982) introduced the autoregressive conditional heteroskedasticity or *ARCH* models. Following Enders (1995), the model is expressed as follows:

---

[1] Usercost is also referred to as rental prices of the monetary assets. It is the price of the transaction service of each monetary asset. See Dahalan (2003) for the detail discussion.
[2] The benchmark rate of return is defined as the maximum expected holding period yield of pure store-of-value asset. The benchmark asset is specifically assumed to provide no liquidity or other monetary service and held solely to transfer wealth intertemporally. See Dahalan (2003) for a detail discussion.

$$v_t = a_0 + a_1 v_{t-1} + \varepsilon_t \tag{6}$$

where v_t in this study is $log(i_t/i_{t-1})$, and i_t is the opportunity cost.

Accordingly, the conditional variance can be modeled by estimating an *AR(p)* process using the squared residuals:

$$\hat{\varepsilon}_t^2 = \alpha_0 + \alpha_1 \hat{\varepsilon}_{t-1}^2 + \alpha_2 \hat{\varepsilon}_{t-2}^2 + \ldots + \alpha_p \hat{\varepsilon}_{t-p}^2 + \mu_t \tag{7}$$

where μ_t is a white noise such that $\{ \mu_t \}$: iid $N(0,\sigma^2)$. In the *ARCH* model, the error structure is such that the conditional and unconditional means of ε_t are equal to zero.

As a way to model persistent movements in volatility, Bollerslev (1986) suggested the Generalized Autoregressive Conditionally Heteroskedastic, or *GARCH* model that allows the conditional variance to be an *ARMA* process. The error process is given here as:

$$\varepsilon_t = \mu_t \sqrt{h_t} \tag{8}$$

and

$$h_t = \alpha_0 + \sum_{i=1}^{p} \alpha_i \varepsilon_{t-i}^2 + \sum_{i=1}^{q} \beta_i h_{t-i} \tag{9}$$

where μ_t is a white noise process such that $\{\mu_t\}$: iid $N(0,1)$ so $\sigma_\mu^2 = 1$. By analogy with *ARMA* models, this is called a *GARCH(p,q)* model.

The volatility of the US and Japanese interest rates is measured using a *GARCH* model (Choudhry, 1999). The first difference of the interest rate, v_t, can be represented in the *GARCH(p,q)* model as:

$$v_t = \mu_t + \varepsilon_t \tag{10}$$

where $\{\varepsilon_t\}$: $N(0,h_t)$. v_t is given as $log(i_t/i_{t-1})$ where i_t is the US or Japanese interest rate and μ_t is the mean of v_t conditional on past information.

Table 1 presents results from the GARCH(1,1) model for the US and Japanese interest rates. The US interest rate is represented by the three-month Treasury bill and Japanese interest rate is represented by callmoney rate.The results show a significant ARCH effect. Also, the shocks to volatility are not explosive since the coefficient on the lagged error term is less than unity. The persistence measure ($\alpha_1 + \beta_1$) is high in all tests, implying permanent shocks to volatility. In addition, Ljung-Box statistics fail to indicate any serial correlation in the standard residuals squared at 5 percent level using eight lags.

EMPIRICAL ANALYSIS

Unit root test

The order of integration of monetary aggregate M2, the scale variable, financial wealth, the opportunity cost, and volatility of the US and Japan interest rates is determined first before the long-run relationship of money demand and the volatility of the US and Japan interest rates are to be examined. The test is to determine whether the variables in the money demand function are stationary or non-stationary in levels and it is to be performed by conducting a unit root test on the level and first difference of the series. Standard tests for the presence of a unit root are based on the work of Dickey and Fuller (1979, 1981), Perron (1988), and Phillip and Perron (1988) for testing the degree of integration of the variables. The augmented Dickey-Fuller (ADF) and Phillips-Perron (PP) tests for a unit root are performed here.

The augmented Dickey-Fuller (ADF) test is based on the following regressions:

$$\Delta y_t = \alpha + \delta t + \gamma y_{t-1} + \sum_{i=1}^{k} \beta_i \Delta y_{t-i} + \varepsilon_t \tag{11}$$

where ! is the difference operator, t is a time trend, y is the time series variable being tested, ε is the error term, and α, δ, γ, and β are the parameters to be estimated.

Under the Phillip-Peron (PP) test for a unit root, the following estimated models are tested for α equal to unity:

$$y_t = \mu + \alpha y_{t-1} + \varepsilon_t \tag{12}$$

$$y_t = \mu + \alpha y_{t-1} + \varepsilon_t \tag{13}$$

$$y_t = \mu^* + \beta^* \left(t - T/2\right)_t + \alpha^* y_{t-1} + \varepsilon_t^* \tag{14}$$

where y_t is the time series variable at time t, and $\hat{\lambda}$, ε_t, and ε_t^* are error terms. These error terms are of the normal distribution with zero mean. Under the PP unit root test, the estimated model in (14) is first tested for a unit root using the test statistics of $Z(\alpha^*)$, $Z\left(t_{\alpha^*}\right)$, and $Z(\Phi_3)$. If the null hypothesis is accepted, then the drift, μ^*, is equal to zero. Then the null hypothesis $H_0 : (\mu^*, \beta^*, \alpha^*) = (0, 0, 1)$ is tested using $Z(\Phi_2)$. If the null hypothesis is accepted then the next null hypothesis of $H_0 : \left(\mu, \alpha\right) = \left(0, 1\right)$ is tested using $Z\left(\alpha\right)$, $Z\left(t_\alpha\right)$ and $Z(\Phi_1)$ to determine if a series has zero mean. If the null hypothesis is accepted, then the series has a zero mean. Therefore, the appropriate model will be one without the intercept or trend.

Tables 2 and 3 present the results from the various forms of the ADF and PP tests on log levels and log first difference series respectively, based on a standard regression with a constant, and with a constant and time trend. The null hypothesis of the existence of a unit root for the log first difference of all series is overwhelmingly rejected. Therefore, we can be conclude that all the series in our sample are stationary in the log first difference.

Cointegration test with Johansen Maximum Likelihood

Even if macroeconomic time series are nonstationary, there may exist some linear combination of these variables that converge to a long run relationship. Individually, if the series are stationary after differencing and a linear combination of their levels is also stationary, then the series are said to be cointegrated. The long-run equilibrium relationship in the money demand function is determined by using the maximum likelihood approach by Johansen (1988) and Johansen and Juselius (1990) in a multivariate setting. The Johansen-Juselius estimation method is based on the error-correction representation of the vector autoregressive (VAR) model with Gaussian errors. The method provides tests for identifying the number of cointegrating vectors between variables. These tests are based on the trace statistic test and the maximum eigenvalue test. It treats all variables as endogenous thus avoiding an arbitrary choice of dependent variable. It also provides a unified framework of a vector error-correction model. Evidence of cointegration diminishes the possibility of the estimated relationship being spurious.

The *kth* order vector autoregressive (VAR) of Y_t is given as:

$$Y_t = \Pi_1 Y_{t-1} + \Pi_2 Y_{t-2} + \ldots + \Pi_{t-k} Y_{t-k} + C + \Phi t + \xi_t, \quad t = 1, 2, \ldots, T \tag{17}$$

$$Y_t = C + \sum_{i=1}^{k} \Pi_i Y_{t-i} + \Phi t + \xi_t \tag{18}$$

where Y_t is a $p \times 1$ vector of I(1) processes. Y_t is a sequence of random vectors with components $(Y_{1t}, Y_{2t}, \ldots, Y_{pt})$. The residuals of this process, $\xi's$, are drawn independently and identically from a p-dimensional Gaussian distribution with covariance Λ and $Y_{-k+1}, Y_{-k+2}, \ldots, Y_0$ fixed. Thus $\{\xi\} \sim iid\ N(0, \sigma^2_\xi)$. C is a constant term and t is time trend.

The first difference form of the VAR model is:

$$\Delta Y_t = \Gamma_1 \Delta Y_{t-1} + \Gamma_2 \Delta Y_{t-2} + \ldots + \Gamma_{k-1} \Delta Y_{t-k+1} + \Pi Y_{t-k} + \Phi t + \xi_t$$

where $\Gamma_i = -(I - \Pi_1 - \ldots - \Pi_i)$ and $\Pi = -(I - \Pi_1 - \ldots \Pi_k)$.

Since Y_{t-k} is I(1), but ΔY_t and ΔY_{t-i} are I(0), it is the Π matrix that conveys the information about the long-run relationship between the Y variables in the model. Π_t is a $p \times p$ matrix which is called a long run impact matrix and the test procedure will examine this Π matrix. In this procedure two likelihood ratio test statistics will be employed.

First, the null hypothesis of at most r cointegrating vectors against a general alternative will be tested by:

$$\text{Trace statistics} = T \sum_{i=r+1}^{p} \ln(i - \lambda_i)$$

Secondly, the null hypothesis of r cointegrating vector against the alternative of $r+1$ will be tested by:

Maximum eigenvalue statistics (λ-max) $= T \ln\left(1 - \lambda_{r+1}\right)$, where λ are the estimated eigenvalues.

Using the multivariate method of cointegrating, we examined if there is any long-run relationship between money demand with the volatility of the US interest rate, and between money demand with the volatility of the Japanese interest rate.

To proceed with the long-run cointegration analysis, the order of the VAR system needs to be determined. The various likelihood ratio (LR) tests are performed and examined for the exclusion of the *(p-1)th* lag. In this study, the general to specific procedure yields the AR model of 8 for both models with the volatility of US and Japanese interest rates. A systematic test procedure for the model specification is performed to examine both the rank order and the deterministic component for the cointegration system simultaneously[3]. Based on the λ-trace statistics at the 5 percent significant level, the procedure suggests a linear trend for the model with US and Japanese interest rates volatility.

The statistical tests regarding the number of cointegrating vector are presented in tables 4 and 5. Result from the test show that at 5 percent level of significance, money demand and other variables i.e consumption, financial wealth, opportunity cost and volatility of the interest rates (US and Japanese) are bound together in the long-run by one cointegrating vector. Normalizing the coefficients of the money demand, the long-run relationships between the money demand in Malaysia with consumption, opportunity cost, volatility of the US and Japanese interest rates, and financial wealth can be expressed as follows:

$$\log(M/P) = 1.695\log(C/P) - 0.439\log R - 0.117\log(VUS) + 0.021\log(FW/P) \qquad (19)$$
$$ (16.845) \qquad (7.281) \qquad (5.273) \qquad (0.296)$$

$$\log(M/P) = 0.968\log(C/P) - 0.121\log R - 0.095\log(VJP) + 0.685\log(FW/P) \qquad (20)$$
$$ (5.757) \qquad (5.091) \qquad (2.427) \qquad (1.083)$$

where *VUS* and *VJP* are the US and Japanese interest rates volatility respectively. Residuals from the systems are tested for serial correlation and reported in Tables 3 and 4. The Ljung-Box and Lagrange Multiplier tests indicate no serial correlation among residuals.

The signs for scale variable, *C* and opportunity cost, *R* are as anticipated in accordance to standard money demand theory. The results indicate an positive relationship between volatility of the US and Japanese interest rates and real money demand in Malaysia. By means of the *t* test, all variables except for the financial wealth (*FW*), are found to be significantly different from zero at 5 percent significance level. The results also indicate a significant effect is imposed by the volatility of the US and Japanese interest rates on the demand for real money in Malaysia. This could be due to the fact that US and Japan are the two major trading partners for Malaysia and the influence could be felt directly. Therefore, any structural change in the interest rates in these two countries will bear some implications toward the demand for real money in Malaysia. The influence of the US and Japanese interest rates volatility can also be explained by the portfolio theory of money demand and transaction demand for money. According to the portfolio theory of money demand and transaction demand for money, an increase in the volatility of interest rates increases the risk of holding fixed-term interest paying securities, and in order to reduce this risk firms and households may wish to hold larger money balances (Garner, 1990). In addition, according Slovin and Sushka (1983) the interest rate volatility can be important because large changes in the interest rate may produce substantial variation in holding period returns for even short-term liquid assets that are sold prior to maturity in order to alter a cash position. This suggest that the risk-averse economic agents will increase their demand for money as the interest rate becomes more volatile.

---

[3] A systematic test procedure for model specification is performed to examine both the rank order and deterministic component for the cointegration system simultaneously.

The results in this study also show evidence that the size of the effect imposed by the opportunity cost, in absolute value, is larger than the effect due to the volatility of the US and Japanese interest rates. Thus, the opportunity cost of holding money still imposes a larger effect on money demand function than the volatility of the US and Japanese ineterest rates. Nevertheless, the results indicate that the US and Japanese interest rates volatility could also play a significant role in influencing the demand for money in Malaysia as such it cannot be totally ignored by the policy makers in formulating effective monetary policy for Malaysia.

CONCLUDING REMARKS

This paper estimates the impact of the foreign interest rates volatility on the money demand in a Malaysia. The US 3-month treasury bill and Japanese call money rates are used to represent the foreign interest rates. The conditional variance estimates of the US and Japanese interest rates obtained from GARCH(1,1) model are applied as the US and Japanese interest rates volatility. By applying the Johansen procedure of cointegration the long-run relationship between real M2, real consumption, the opportunity cost of holding money, and real financial wealth, firstly with the US interest rate volatility, and secondly with Japanese interest rate volatility are determined.

The results show that the larger effect in money demand function in Malaysia imposes by opportunity cost as compared to the effect imposes by the volatility of the US and Japanese interest rates. However, the results indicate that the volatility of the US and Japanese interest rates have a significant role in money demand function in Malaysia given the fact the US and Japan are the main trading partners for Malaysia. As such, the role of the volatility of the foreign interest rates (US and Japanese) in formulating the effective monetary policy in Malaysia cannot be totally ignored.

ABSTRACT

The impact on the performance of firms in Malaysia due to corporate practices and structures was analysed based on data involving 120 Malaysian listed companies over a four-year period from 1996 to 1999. This period encompassed the 1997/98 Asian financial crisis which affected most countries in the Southeast Asian region including Malaysia. Due to the combination of cross-sectional and time-series data, panel data regression techniques were used to analyse performance of the firms using both fixed effects and random effects models. Using return on equity as the dependent variable, it was established that the size of firm, gearing ratio (borrowing) and the proportion of share owners in the firm accounted for by institutional investors significantly influenced the performance of firms. The impact of size on the performance of firms followed a quadratic fashion with performance increasing with the size of the firm up to the optimal size of around 8,839 million ringgit. Beyond that, firm performance declined with increasing size. Borrowing had a negative effect on earnings with 1% increase in borrowing having a 0.14% decrease in return on equity. Finally institutional investors exerted a positive influence on company earnings. The increasing presence of institutional investors would appear to be a good strategy to increase the performance of firms.

INTRODUCTION

Poor governance standards in both corporate entities and government were blamed in part for the East Asian financial crisis. In Asia, corporations tend to follow the 'insider' model with dominant control by owners and large shareholders (Sycip, 1998; Yamazawa 1998). The erosion of investor confidence was identified as one of the major factors that exacerbated the financial turmoil in Malaysia and a number of Asian countries. Many commentators, for example, Noordin (1999) argued that the erosion of investor confidence in Malaysia was brought about by the country's poor corporate governance standards and lack of transparency in the financial system. The restoration of full confidence in the economy by investors would rely on the improvement of corporate governance standards including the adoption of transparency as an important strategy in corporate management. The paper focuses on the corporate practices of the Malaysian companies and attempts to measure its impact on firm performance. Certain corporate structures and practices are examined to determine if they have any effect on company's performance, and these are:

   a. The role of lenders in corporate governance
   b. The governance role of independent directors
   c. The CEO duality structure
   d. The governance role of institutional investors
   e. The concentrated ownership structure
   f. The governance role of audit committees

LITERATURE REVIEW

a.   The Role Of Lenders In Corporate Governance

The role of lenders as a force in corporate governance has not yet been extensively analyzed (Prigge, 1998). Lenders are interested in the repayment of a credit in accordance with the credit contract. Since management's actions are one of the factors determining repayment, lenders may be motivated to carry out monitoring. Billimoria (1997) found evidence to indicate that CEO's of highly leveraged firms were paid less long-term pay.

b.   The Governance Role Of Independent Directors

Byrd/Hickman (1992) report that tender offer bidders with majority-independent boards earn roughly zero stock price returns on average, while bidders without such boards suffer statistically significant losses of 1.8% on average. You et all. (1986) also report a significant negative correlation between proportion of inside directors and bidder stock price returns. This suggests that independent directors may help to restrain the CEOs tendency to build a larger empire, even if this means overpaying to buy another company. Denis/Sarin (1997) report that firms that substantially increased the proportion of independent directors had above-average stock price returns in the previous year. In a study to assess investor reaction to the appointment of additional directors, Rosenstein/Wyatt (1990) found that stock prices increase by about 0.2% on average, when companies appoint additional outside directors. This increase was statistically significant, but economically small.

c.   The CEO Duality Structure

Rechner and Dalton (1991) examined the relation between CEO duality and organizational performance. Their study supports agency theory expectations about inferior shareholder returns from CEO duality. Rechner and Dalton (1989) also examined the effect of CEO duality on risk-adjusted shareholder returns using stock market data for the same sample and period. They found no significant difference between structures. Donaldson & Davis (1991) examined the effects of CEO duality on shareholder returns, and recorded exactly the opposite result to that of Rechner and Dalton (1991). Their results show that the average return on equity of the board with chairs independent of the CEO was 11.5%, less than the average ROE of those companies with CEO duality at 14.8%. The difference was statistically significant, i.e. dual CEO structures outperform independent chair structures.

d.   The Governance Role Of Institutional Investors

Large outside (institutional) shareholders are regarded as an effective monitoring mechanism for a number of reasons. For example, they have a vested interest in minimizing any asymmetry of information which may exist and will therefore vote in accordance with their own interests (Jarrell & Poulson, 1987). In addition to the monitoring role, Shleifer & Vishny (1986) also argue that large outside shareholders assist the market for corporate control simply by being willing to sell their shares should an appropriate bid be made. They, therefore have an incentive to monitor the behavior of managers which should solve the free-rider problem identified by Grossman & Hart (1980).

e.   The Concentrated Ownership Structure

As regards the relationship between ownership concentration and firm performance, empirical results in the U.S. are inconclusive. Demsetz & Lehn (1985) found no significant correlation between ownership concentration and profit rates for 511 large corporations. Morck et al. (1988) reported a piecewise linear relationship of Tobin's Q with board member ownership for 371 Fortune 500 firms, and also found evidence of an inverted "U"-shaped relationship between the degree of ownership concentration and profitability. Stulz (1988) demonstrates that higher managerial ownership can insulate managers from external takeovers, and by allowing managers to block takeover bids, can lower firm value. Using U.S. data, Morck et al. (1988), McConnell & Servaes (1990, 1995), Hermalin & Weisbach (1991), and Holderness et al. (1999) all find firm value to rise with low levels of managerial ownership and to fall with higher levels of managerial ownership.

f.   *The Governance Role Of Audit Committees*

Several empirical studies in accounting have focused on the voluntary formation of audit committees to identify factors affecting an entity's decision to create an audit committee directly responsible for overseeing the financial reporting process (Pincus et al., 1989). Collectively, these studies suggest that larger companies, who are audited by the Big 5 and who have bigger boards with greater representation of outside directors, are among the companies more likely to voluntarily form an audit committee. Several studies document that the presence of an audit committee is associated with fewer incidences of financial reporting problems.

METHODS AND PROCEDURES

Data were gathered on 120 Malaysian public listed companies during the period 1996 to 1999. The samples were public companies fully quoted either on the main board or the second board of the Kuala Lumpur Stock Exchange (KLSE). A large majority of the companies selected (87%) comes from the main board. The samples covered all sectors of the economy and are reported in Table 1 below. The samples were drawn from twenty volumes of KLSE Annual Companies handbook on a random basis until the required quota is reached. The sample selected is line with other previous research on this area, e.g. Yeboah-Duah (1993) studied a sample of 210 Malaysian firms for the period 1984-1991, Mat-Nor et all (1999) uses 79 Malaysian firms, Ruhani Ali and A. U. Sanda (2001) uses 112 KLSE listed firms covering the period 1992-1997, and Yap (2001) uses 69 KLSE companies covering the period 1995-1999.

Dependent Variables

This research utilizes commonly used accounting measures of performance of PLCs as its dependent variables, namely return on equity (ROE) and dividend payouts (DIVPAY). The dividend payout is the percentage of dividend declared for the year and is equivalent to the returns to the shareholders in cash terms. The dividend payouts were extracted from the figures given in the KLSE handbook. The other dependent variable tested is the return on equity (ROE), defined as earnings divided by total ordinary shareholders' fund. These figures were also obtained from the KLSE handbook. Dependent variables were employed as proxy for firm performance. A high score for each of the variable signifies favourable financial performance.

Independent Variables

The independent variables are factors that influences firm performance, and they affect either return on equity (ROE) or dividend payout by driving them up or down. Seven (7) independent variables were selected. They are represented by:
1. NED - measures the proportion of non-executive directors on the board of directors, expressed as a percentage. It is defined as the number of non-executive directors divided by the total number of directors on the board of the company. The co-efficient's expected sign is positive, i.e. the higher the proportion, the more independent is the board in making decisions. This implies better company performance, measured by the dividend payout and return on equity ratio.
2. CHAIRAC - a binary variable. If the chairman of the audit committee is a non-executive director, it is coded one, otherwise zero. This serves to test the degree of independence of the audit committee. An independent chairman is expected to contribute to a more rigorous regime of monitoring and therefore improves performance of the company.
3. CEOCHAR - a binary variable. If the positions of the chief executive officer and the chairman are filled by a single person, the variable has the value of one, and zero if they are not. The coefficient's expected sign is positive. This is because the effectiveness of the board as an internal governance devise will be perceived to have been compromised by the roles not being separated.
4. INST - measures the proportion of large institutional investors. The higher the proportion, the greater is the monitoring role of institutional investors. It also implies that managers of companies would be under pressure to perform to the expectations of institutional investors. The coefficient is expected to be positive.
5. GEAR - measures the proportion of large borrowings. It is a gearing ratio and is defined as long-term borrowings/debt divided by total shareholders ordinary fund plus long-term debt. The coefficient is expected to be positive since greater borrowings imply that lenders/banks will be expected to play a greater monitoring role.

6. CONCEN - measures the proportion of concentrated ownership. The higher the proportion, the greater is the monitoring role of large owners. This is in line with agency theory which hypothesized that greater ownership would reduce agency costs and hence improves performance. The coefficient is expected to be positive.

7. SIZE - captures the size of the company in terms of turnover. Size is expected to be a positive influence on company performance due to greater diversification, economies of large scale production and greater access to new technology and cheaper sources of funds. The coefficient is expected to be positive.

MONITORING MEASURES

Six measures of monitoring were used in this study. These are divided into two types: internal or external monitoring measures.

A. Internal Monitoring Measures

The first internal monitoring measure is the ratio of the number of outside (non-executive) directors to total directors (i.e. inside and outside directors), a measure commonly used by researchers to measure corporate control (e.g. Morck, Shleifer & Vishny, 1988; Weisbach, 1988; Beatty & Zajac, 1994). The second internal monitoring measure is the dichotomous CEO/chairman variable, indicating whether the CEO position is separated from the chairman of the board. The third internal monitoring measure is the presence of an independent audit committee who can be expected to monitor firm performance and give advise. The fourth monitoring measure is the presence of concentrated ownership who by virtue of their large shareholdings will increase their monitoring as their proportion of share capital increases.

B. External Monitoring Measures

The first external monitoring measure is the presence of large creditors, i.e. bank debt. Banks are expected to use their influence as lenders to monitor management to ensure repayment of their principal and interest in the future. The second monitoring measure is the presence of a shareholder with large equity holdings (greater than 5%) who is not on the board (i.e. a blockholder or institutional investors).

HYPOTHESES

H1: Ceteris paribus, a firm's financial performance will be positively related to sound internal corporate governance structures, i.e. internal monitoring measures.

H2: Ceteris paribus, a firm's financial performance will be positively related to monitoring by external stakeholders, i.e. external monitoring measures.

MODEL SPECIFICATION

Most of the literature uses univariate and multivariate logistic regression analysis, or multiple linear regressions to test the firm's value and ownership (Weir, 1997). The method used in this analysis is the pooled ordinary least squares (OLS), applying cross sectional time series standard multiple regressions. Two models are formulated; one based on dividend payouts (DIVPAY) and the other is based on return on equity (ROE) as the dependent variables. H1 and H2 are tested using the following OLS model. The model based on ROE is formulated as follows:

$$ROE_t = a + bNED_{t-1} + cCHAIRAC_{t-1} + dCEOCHAR_{t-1} + eINST_{t-1} + fGEAR_{t-1} + gCONCEN_{t-1} + hLogSIZE_{t-1}.$$

Where;   DIVPAY = dividend payout in percentage
            ROE = Return on Equity ratio
            NED = Non-Executive Directors
            CHAIRAC = Chairman of the Audit Committee
            CEOCHAR = Chief Executive Officer and Chairman of the Board
            INST = Institutional investors

GEAR = Gearing ratio
CONCEN = Concentrated Ownership
LogSIZE = Logarithm of Size of Firm

PANEL DATA REGRESSION ANALYSIS

The ordinary least squares (OLS) regression that was done earlier produced relatively low R squared value and low Durbin-Watson statistics. An examination of the F-test and its P-value clearly indicate that the OLS method was not appropriate (Leamer, 1978). This is because the data under study are panel data or sometimes referred as pooled data or combination of time series and cross-sectional data. Such data requires the use of panel data regression models in order to obtain meaningful results. There are two most frequently used estimation techniques to address these problems, namely the fixed effects model (FEM) and the random effects model (REM) (Gujarati, 2003, chapter 16).

Regression Analysis

The data collected were for the period 1996-1999 (four years) and involved 120 companies. However, only 77 companies were eventually analyzed by the econometric software, Time Series Processor (TSP) version 4.5, due to the presence of outliers and also automatic rejection of incomplete data. Only the dependent variables are expressed in natural logarithm form. Also, another variable was added, namely size-square (sizesq) to test the possibility of a quadratic/curvilinear relationship involving size of company.

RESULTS

The test results showed that for both models, the hypothesis that there was a single set of slope of coefficients and one overall intercept, was rejected (based on the F test, Leamer, 1978 p. 114). The F test analysis involved a separate regression for each individual company. F tests for equality within the TOTAL and WITHIN estimators were derived. In addition, the low value of R squared and judging from the Durbin-Watson statistic for testing that P value equals zero, there is some possibility that a first-order serial correlation of the disturbances will occur. Subsequently, estimation techniques involving the fixed effects and random effects models were used. The results obtained from using these techniques were obviously better, judged by the statistical significance of the estimated coefficients and the high value of R squared. The Hausman specification test confirmed the superiority of the fixed effect models over the random effect models. Hence, further interpretative work and discussions only involve the fixed effects model. The results are summarised in Table 1. Using logged return on equity (LROE) as the dependent variable, three significant variables were obtained at the 10% significance level. The estimated value of the R squared is 0.793 which implies that 79% of the variations in earnings can be explained jointly by the seven independent variables. Also the F-statistic (5.85) is significant at the 1 percent level. Thus, overall the model is a strong one.

Table 1: Results of the fixed effects model (FEM) regression analysis using the natural logarithm of return on equity (LROE) as the dependent variable.

Variable	Estimated Coefficient	Standard Error	t-statistic	P-value
NED	-0.0048	0.006	-0.7895	[.431]
CONCEN	-0.0022	0.0106	-0.2108	[.833]
SIZE	0.0009	0.0004	2.0615	[.041]*
SIZESQ	-0.00000005	0.00000002	-2.4396	[.016]*
INST	0.0201	0.0118	1.7061	[.090]*
GEAR	-0.6879	0.1328	-5.1813	[.000]*
CHAIRAC	-0.5734	0.3691	-1.5534	[.123]
CEOCHAR	0.3904	0.261	1.4957	[.137]

R-squared = .7931   Adjusted R-squared = .6682   LM het. test = .3031 [.582]**

Notes:
(1) * denotes statistical significance at 10% level
(2) ** The p values are in brackets

The significant findings relate to the following three independent variables:

INST – The estimated co-efficient is 0.02. This is statistically significant at 10% level, and can be interpreted as: a 1% increase in institutional shareholdings leads to 0.213% (0.02 by 10.665) increase in return on equity given that the mean of institutional holdings is 10.665. For a log-lin (semi-logarithmic) function, the elasticity is the coefficient estimate multiplied by the value of the independent variable. In this study, the mean value of institutional holdings is used (refer to Table 2).

GEAR – The resulting co-efficient is a negative 0.688. The parameter estimate is highly significant (at 0.000 level). It can be interpreted as: 1% increase in gearing leads to a 0.14% (0.688 by 0.20) decrease in return on equity.

SIZE - The resulting co-efficient is 0.02. The results showed that company size in terms of turnover does influence earnings. It seems that a higher turnover leads to higher return on equity. However, further analysis using size-squared indicated a parabola shape curve of size over earnings. This is interpreted as: the larger the company, the better the earnings, but when the company gets too large, earnings began to taper off. By using algebraic differentiation, it is found that earnings are maximized at the turnover level of 8,839 millions or about 66% of the maximum (turnover) size of 13,294 millions.

CONCLUSIONS AND POLICY IMPLICATIONS

There were major significant findings in this study. Out of the seven independent variables that were hypothesized to influence return on equity (ROE), three of these were found to have a significant a major impact on ROE. This finding has some policy implications. The three independent variables which were found to be significant are the influence of institutional investors, gearing (borrowing) and size of company. The results of the latter two variables are expected and are in accordance with the accounting and finance literature. These two variables (gear and size) can actually be termed control variables in this study as the findings are not related to corporate governance structures. The results relating to gearing (borrowing) can be explained as follows: and increase in borrowing burdens the companies with interest payments which are directly charged to the income statement, thus dampening profits. This explains the negative sign for the resulting coefficient. However, according to the literature on corporate governance, high borrowing encouraged the banks and creditors to monitor the company and therefore is expected to contribute to higher profits through investments in value enhancing projects. The results obtained clearly indicated that this is not the case in Malaysia. Banks do not perform such value-enhancing role. The second significant result relating to size is a new contribution to the Malaysian corporate literature because this is the first case to prove that size has been positively identified with earnings. Furthermore, the study identified that the curve function of size against earnings as a parabola and maximized at RM8,839 millions. The study thus proves that even though size matters when it comes to earnings, there is a limit, and a corporation which has become too large can be counterproductive. This can be explained in terms of managers favoring empire building at the expense of the productivity of the company. It can also indicate the CEO's inability to exert control and lack the technical expertise to run large enterprises. The current corporate trend in the USA and Europe is to focus on its core business and get rid of unrelated businesses for which top managers know very little. The study provides evidence that Malaysian companies may have to follow such an example. The third significant variable (inst) is the only one that relates corporate governance structures to firm performance. This finding has been rather surprising as institutional investors are not generally known to be active in monitoring the companies they had invested in Malaysia. The result show a somewhat small increase in earnings of 0.213% for each 1% of institutional holdings in Malaysian companies. This may indicate foreign institutional influence that could prompt Malaysian managers to make value-enhancing decisions. It could also reflect that managers maybe aware of the intense monitoring done by institutional investors and therefore less inclined to expropriate company assets. The small influence of institutional investors indicate that these group is not actively exerting their influence through shareholder activism. Their influence rests in their ability to exit enmasse and such actions could result in a fall in share prices.

Contrary to some written literature, it is found that non-executive directors in Malaysia have no influence on ROE, i.e. profitability of the company. It seems that these non-executive directors are not really independent enough to play a serious monitoring role, and the results seems to indicate that they are not of high calibre to contribute significantly to firm performance. The results also indicate that even if the non-executive directors are a majority on the board, it has not significantly influenced ROE, signifying the lack of independence which is expected of them. The results have shown that audit committees chairman who are non-executive directors in these companies do not play a significant role in influencing ROE. The fact that the chairman of the audit committee is a non-executive director has no bearing on performance. The same is also true even if the majority of committee members are non-executive directors. This can be explained in terms of the committee's lack of independence and skill required from the members. The KLSE has

therefore proposed that members of the audit committee should preferably be qualified accountants. The existence of a dominant personality where the CEO is also the chairman of the board has no bearing on company performance. The debate in the U.K. to separate the roles of the CEO from the chairman of the board seems to be inapplicable to Malaysian firms. It is a shared responsibility of the board to ensure firm performance. Concentrated ownership in these companies has no bearing on company performance and the argument that large blockholders align their interest with the company is not true in Malaysia. According to the agency theory, large blockholders solve the agency problems partially and reduce costs. However, since they have control rights, they maybe in a better position to expropriate company assets and exploit the interest of the minority. Therefore, the owner-managers may have worked hard to increase earnings but these earnings maybe used to enrich themselves, resulting in the company's performance remaining unchanged.

A Different Perspective of Service for Licensed Financial Planner

Bryan Lo, Geoffrey H. Tanakinjal and Airulamri Amran
Labuan School of International Business and Finance
Universiti Malaysia Sabah, Sabah, Malaysia

ABSTRACT

In the past, the designation financial planner has been widely used by the individual intermediaries of the financial institutions. These individual intermediaries are mainly representatives in marketing financial services especially in life insurance and unit trusts for their companies/principals. Therefore, the financial planner designation has been coined for these professions in the eye of the public. The confusion increased when the Securities Commission had on 5 January 2004 amended the Securities Industry Act 1983 to license a financial planner. Who is actually a financial planner? This paper discusses the fundamental of services and differentiates between a service distributor and a service provider that determine the role of a licensed financial planner. In addition the relevant services marketing strategies are also recommended for practice.

INTRODUCTION

Since the Securities Commission emphasized the development of the financial planning industry under the Capital Market Master Plan in 2001, the term financial planning or financial planners have been the buzzwords for the general public. If we ask any Malaysian on the street what is financial planning or financial planner, most of them would relate it to insurance services, unit trusts and lately including the will writing services. This could be due to the past impression projected by the individual intermediaries from these industries holding themselves as financial planner, financial consultant or financial advisor. Those individual intermediaries who used the above mentioned designations are only marketing or selling financial services on behalf of their companies/principals. Although being identified as financial planner, most of the time they are only distributing the financial services to their customers. There are no actual financial planning services being delivered. If there is, are very minimal act. Hence, these individual intermediaries are merely financial service distributors ("FSDs"). In fact financial planning is not new in Malaysia. In the past decades, some professions from different backgrounds such as accountants, lawyers, investment analyst, and securities brokers have already been providing some form of financial planning services to their customers. These professionals who advise or consult are indeed engaged in financial planning services process, at least partially if not in full-scale service. Therefore, it is the practice of financial planning which has been introduced as a profession by the authorities that may have created some curiosity to the public. The recent licensing requirement enforced by the Securities Commission on 5 January 2004 has further spurred the excitement of existing FSDs as well as the potentials in grabbing the financial planner license. The question here is "are the FSDs aware of the changing role a Licensed Financial Planner ("LFP") or just rushing to change their designation for competitive advantage"? This paper discusses the fundamental of financial planning as a Service that provides insight for the FSDs.

THE FUNDAMENTAL OF SERVICES

"Service is an act or performance offered by one party to another" (Lovelock et al., 1999, p. 5). Another short definition by (Zeithaml,et al., 2003, p.3) is, "Services are deeds, processes, and performances". A service process can be distinguished between a core service and supplementary service. Core service is the main service demanded and consumed by a consumer in exchange of a price, whilst supplementary service is subordinate to the core service, with minimum charge or free (Lovelock, 2001). On the other hand, customer service is a separate process that is provided in support of a company's core products (Zeithaml et al., 2003, p. 4).

Services are intangible in nature which cannot be seen, touch and felt. Therefore, all intangible form of products is classified as services. Services are performances that are difficult to standardize as compare to physical goods. One service delivery varies from another. The production of services is simultaneously with consumption. This makes customer involve in the service production process, failing which a service transaction may not be possible concluded. Researchers also claimed that services are perishable and cannot be inventoried. Hence services have to be consumed during the moment of truth where consumers must participate and experience in the service delivery (Rust et al., 1996); (Lovelock et al., 1999); (Zeithaml et al., 2003).

Services cover a wide range of industries (Zeithaml et al., 2003) including all economic activities whose output is intangible, simultaneous production and consumption, and provides added value in forms such as

convenience, amusement, timeliness, comfort, or health to a purchaser (Quinn et al., 1987). In short, any intangible processes and performances rendered in exchange of a price between service providers and consumers can be termed as services. Fundamentally, marketing of services is different from physical goods. (Rust et al., 1996); (Hoffman et al., 1997); (Lovelock et al., 1999); (Fitzsimmons et al., 2001); (Lovelock, 2001); (Zeithaml et al., 2003).

FINANCIAL PLANNING SERVICES VS FINANCIAL SERVICES

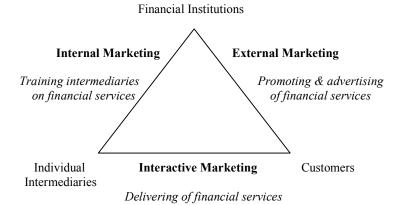
What is a Financial Planning Service? According to the Financial Planning Association of Malaysia ("FPAM") the definition of financial planning is "the process of formulating, implementing and monitoring multifunctional decisions that enable an individual or family to achieve financial goals" (IPFA, 2000, p 1.1). While (Madura, 2002) defined financial planning as the process of planning one's spending, financing, and investing so as to optimize his or her financial situation. Financial planning is a service in nature as it is a process of delivering advisory by a financial planner to a customer. It is a process with a particular method of operations or a series of actions, typically involving multiple steps that often need to take place in a defined sequence (Lovelock et al., 2002). Financial planning services is directed at people's minds. On the other hand, financial services are financial products such as banking facilities and unit trusts produced and marketed by financial institutions. Please refer figure 1. It is also a process and performance service. However, producing of financial services is directed at customers' intangible assets which mainly involve in information processing (Lovelock et al., 2002). Hence, providing financial planning services and marketing of financial services are entirely separate duty and processes. Nevertheless, financial planning services may be different from financial services but it is complementary to the latter.


Figure 1: Financial Planning Services vs Financial Services

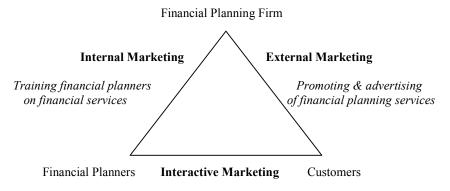
5. Implementing and Monitoring Financial Plan	5. Derivatives

FROM SERVICE DISTRIBUTOR TO SERVICE PROVIDER

Presently, the "financial planning services" industry is still being wrongly conceived and perceived by the general public and the individual intermediaries themselves. As an employee or an agent of the financial institutions, the FSDs' duties are mainly engaging in service distribution. This is depicted in figure 2.

Figure 2: The Services Marketing Triangle


(Source : Adapted from Mary Jo Bitner, "Building Service Relationships: It's All About Promises," Journal of the Academy of Marketing Science 23, 4 (1995): 246-51; Christian Gronroos, Service management and Marketing (Lexington, MA: Lexington Books, 1990); and Philip Kotler, Marketing Management: Analysis, Planning, Implementation, and Control, 8th ed. (Englewood Cliffs, NJ: Prentice Hall, 1994), p. 470).

The financial institutions are the actual service providers in producing and marketing of financial products such as banking facilities and unit trusts. The entire service process started from the financial institutions by developing financial services. The financial institutions would then communicate their financial services to the

customers as well as training the FSDs for further delivery to the customers during the moment of truth. Therefore, most of the time the FSDs are engaging in service delivery while the service providers are responsible for the service quality control. However, the scenario would be different if the FSDs were to practice financial planning services. Please refer figure 3.

Delivering of financial services

(Source : Adapted from Mary Jo Bitner, "Building Service Relationships: It's All About Promises," Journal of the Academy of Marketing Science 23, 4 (1995): 246-51; Christian Gronroos, Service management and Marketing (Lexington, MA: Lexington Books, 1990); and Philip Kotler, Marketing Management: Analysis, Planning, Implementation, and Control, 8th ed. (Englewood Cliffs, NJ: Prentice Hall, 1994), p. 470).

Those FSDs who qualified or hold themselves as LFPs must aware that they are no longer a service distributor. They are engaging in service production and development. The LFPs' duties encompass of communicating the availability of services and delivery of services to the customers. At the same, educating the staff or partners on the firm's services to meet customers' expectation and perception.

In the past practice, the FSDs' responsibility in service quality may be lighter as compare to a full-fledge LFP. This is due to the fact that FSDs' quality control focus is more on customer service. However, a LFP has to manage service quality from the basic of core service to supplementary service to customer service. Hence to ensure providing successful financial planning services to customers, the LFPs must apply services marketing concepts and strategies.

SERVICES MARKETING STRATEGIES FOR FINANCIAL PLANNERS

From the earlier service review, we are aware that managing and marketing of services are different and more challenging than any physical goods. Therefore, the marketing strategies adopted for services are also different from physical goods. The following services marketing strategies are recommended for LFPs to evaluate prior embarking their financial planning service.

New Service Development

Since financial planning services are not financial services, LFPs are required to develop their own services as a service provider. The service development stage is of critical to LFPs because the services designed and offered to customers would determine the success rate of a particular financial planning business. Basically, financial planning services are advisories covering Retirement and Estate planning; Investment planning; Insurance planning; Education planning; Assets Management; Tax planning; and Risk management which serve as the core services. However, the fundamental of services process is depends on one's design and innovation. According to (Fitzsimmons et al., 2001) innovation of new services is the process of creating something new with actual product or outcome. As compare to physical goods, developing and innovating new services are more flexible due to its variation. Hence, the most important factors to be considered for effective planning and developing of new financial planning services are objectivity, service must be precise, fact driven and have methodology (Shostack, 1984). Most of the core services are attached with supplementary services such as billing and safekeeping of documents (Lovelock et al., 2002). Therefore, identification and incorporating of supplementary services would enhance the overall financial planning services. A well designed service process

which is far more complicated than physical goods must be documented as a blueprint, use as a guide to control service operations flow.

Service Quality

When ask the FSDs what is service quality. They may equate it with providing quality customer service to meet customer satisfaction. However, service quality is the entirety outcome and experience that a customer judged on the service consumed (Johnston et al., 2001); (Lovelock et al., 2002). The word quality may sometimes create confusion in services as many people use it interchangeably with the word satisfaction. Quality is viewed as long-term, cognitive evaluations of a firm's service delivery, whereas customer satisfaction is a short-term emotional reaction to a specific service experience (Rust et al., 1996). LFP engaging in service business must put greater emphasis in service quality control because it provides the consumer's overall impression of the relative inferiority/superiority of the organization and its services (Bitner et al., 1994). On the other hand, improving service quality may increase customer's perception on better quality which serve as a competitive advantage. In turn, it would leads to higher corporate profits (Buzzell et al., 1987). Like any other services, financial planning services would be perceived by customers as multiple dimensions (Zeithaml et al., 1993). Five dimensions of service quality (Zeithaml et al., 1990) which a LFP must focus are:

- Reliability - are the LFPs dependable in providing financial planning services as promised, over time?
- Tangibles - what are the physical evidence of the LFPs' services that can increase customer's confidence?
- Responsiveness - are the LFPs helpful and able to provide prompt service?
- Assurance - are the LFPs knowledgeable, competent, polite, and trustworthy?
- Empathy - do the LFPs provide caring and personalized attention?

Reliability is one of the most important factors because it is an outcome measure judged by the customers after the service experience. Meantime, the other four dimensions should be controlled carefully during the moment of truth, as customers would evaluate during the process of delivery (Lovelock et al., 2002).

Service Promotion and Education

When a FSD market and distribute financial services on behalf of the financial institutions, they are not required to invest in marketing communication. Most of the time, the financial institutions are doing the promotion for their own financial services. The scenario is different for FSD who turning into a LFP. As a service provider, LFP need to adopt marketing communication for business success. As depicted in figure 3, LFP need to promote their services to the customers which is known as External Marketing. However, since financial planning services are intangible in nature effective communication strategies need to reflect the special characteristics of services (Mortimer et al., 1998). No doubt, intangible services are more challenging to promote. Therefore, LFP should create tangible effects such as memorable logo or metaphors for the services offered in order to capture customers' attention, interest, and perception. The only way to make customers remember the unseen services all the time is to have consistent and continuous communication. Promoting services shall not limited to its features only because the promises set must be able to meet customers' expectation. Since customer is involves in service production, they have to be educated on the service process so that they aware and prepare mentally for the future consumption of the service. Their knowledge on the service process would ensure certain level of service quality during the service delivery. Service promotion and education would reflect what are the actual service processes the customers expect. Education also needs to be extended to the internal staff as well in order to keep the promises that had set during the marketing communication.

Building Competitive Advantage

In the business world, there is no person can capture all the market and conquer everything. Lovelock stressed that it is not realistic to capture all the customers as there are too many, widely scattered, and too varied in their needs, purchasing behavior, and consumption patterns. Company need to focus its effort on those customers it can serve best (Lovelock, 2001). How do the LFP focus and differentiate themselves from competitors? According to Johnston, there are four focus strategies to create a niche (Johnston, 1996). Please refer figure 4.

Figure 4: Basic Four Strategies for Services

Breadth of Service Offerings

	Narrow	Wide	
	Service Focused	Unfocused (Everything for everyone)	Many
			No. of Markets Served
	Fully Focused (Service & Market Focused)	Market Focused	Few

(Source: Robert Johnston, "Achieving Focus in Service Organisations," The Service Industries Journal 16 (January 1996): 10-20)

A *fully focused* firm provides a very limited range of services to a narrow and specific segment. This strategy would enable the LFPs to concentrate in serving a specific market segment with specialized services. For those LFPs with a pool of specialized human resources, market-focused can be adopted. A *Market-focused* firm concentrates on a narrow market segment but has a wide range of services. Meantime, LFPs with limited human resources can consider *Service-focused* strategy which offer a narrow range of services to a fairly broad market. Finally, *Unfocused* means firms that try to serve the broad markets by offering everything for everyone. LFPs are discouraged to stay in this position, as it would be detrimental for business in the long-term.

Based on Johnston' Basic Four Strategies model, it can help LFPs to craft a niche on which and what market segment to target at.

CONCLUSION

The key highlight on this paper is on the fundamental differences between a FSD and LFP. This would serve as reminder for any FSD who wish to practice as a LFP so that they would expect to change their role as a service distributor to a service provider. The service marketing strategies discussed also provides an insight for LFP to evaluate on their practices. In conclusion, the success transition of a FSD to a LFP would all depends on the changing mindset and perception on the fundamental of services of a "financial planner".

ABSTRACT

This study utilizes the windowed-test procedure of Hinich and Patterson (1995) to examine the data generating process of KLSE CI returns series. Our econometrics results indicate that linear and non-linear dependencies play a significant role in the underlying dynamics of the returns series, implying the potential of returns predictability. However, these dependency structures are not stable and persistent across time as the results reveal their episodic and transient behaviour, and hence do not bring much benefit to investors. Moreover, for most of the time periods, the returns series move along at a close approximation to random walk. As a whole, the results do not constitute strong evidence against the weak-form EMH in KLSE.

INTRODUCTION

The efficient market hypothesis (EMH) introduced three decades ago was a major intellectual advance and much research endeavour has been devoted over the years to examine the efficiency of stock market price formation, both in developed and emerging stock markets. The phenomenal growth in this body of literature is partly due to the concern and interest of financial economists and investment communities on the predictability of stock prices. Within this framework, the random walk theory of stock prices, which postulates that future price movements cannot be predicted from historical sequence of stock prices, has been widely employed to test the efficiency of stock market, particularly in the context of weak-form efficiency. The justification is that in an efficient market, new information is deemed to come in a random fashion, thus changes in prices that occur as a consequence of that information will seem random. Therefore, price movements in a weak-form efficient market occur randomly and successive price changes are independent of one another.

Over the past two decades, the efficiency of the Kuala Lumpur Stock Exchange (KLSE) of Malaysia has received considerable attention from researchers. Generally, the empirical evidence reported suggests the market is weak-form efficient, for instance, Barnes (1986), Laurence (1986), Saw and Tan (1989), Annuar *et al.* (1991, 1993), Kok and Lee (1994) and Kok and Goh (1995), just to name a few. However, empirical evidence of inefficiency cannot be suppressed, which is documented in Yong (1989, 1993). Another recent study by Lai *et al.* (2003) using the variance ratio test also reveals the non-randomness of successive price changes in the KLSE.

Though the empirical results on the KLSE are mixed, one notable similarity of all the aforementioned studies is the application of standard statistical tests- serial correlation test, runs test, variance ratio test and unit root tests, to uncover linear serial dependencies or autocorrelation in the data. However, the lack of linear dependencies does not imply that the series are random as there might be other more complex forms of dependencies which cannot be detected by these standard methodologies. Even Fama (1965: 80) admitted that linear modelling techniques have limitations, as they are not sophisticated enough to capture complicated 'patterns' that the chartist sees in stock prices. Steurer (1995: 202) expressed similar opinion, in which he argued that there is an

order to the apparent randomness of the market. This order is so complex that the random walk concept is proven by the standard linear statistical tests. Another researcher, Brooks (1996: 307) agreed that series of financial returns often appear completely random to standard linear and spectral tests. However, the author strongly believed that if a different approach, using more powerful techniques, it may be possible to uncover a more complex form of dependencies in these series.

One of the possibilities that might contribute to the departure from random walk is the presence of non-linear serial dependencies in the underlying data generating process (DGP). Even the influential paper of Fama (1970: 394) acknowledged this possibility, "*Moreover, zero covariances are consistent with a fair game model, but as noted earlier, there are other types of nonlinear dependence that imply the existence of profitable trading systems, and yet do not imply nonzero serial covariances*". In this regard, Hinich and Patterson (1985) is the first published paper reporting evidence of non-linearity in common stock returns. As recalled by Patterson and Ashley (2000), the original manuscript of Hinich and Patterson (1985) met with resistance from the finance journals because finance academics were reluctant at that time to recognize the importance of distinguishing serial correlation from non-linear serial dependencies. Subsequent evidence documented in Scheinkman and LeBaron (1989), Hsieh (1991), Abhyankar *et al*. (1995, 1997), Barkoulas and Travlos (1998), Opong *et al*. (1999) and Ammermann and Patterson (2003) strongly suggest that non-linearity is a cross-sectionally universal phenomenon.

The evidence of non-linearity has strong implication on the weak-form EMH for it implies the potential of predictability in financial returns. Specifically, if investors could have profitably operated a trading rule (net of all transactions costs) that exploits this detected non-linearity, it would be at odds with the weak-form EMH, which postulates that even non-linear combinations of previous prices are not useful predictors of future prices (Brooks, 1996; Brooks and Hinich, 1999; McMillan and Speight, 2001). However, Hsieh (1989) argued that the standard statistical tests such as serial correlation test, runs test, variance ratio test and unit root tests may fail to detect non-linear departure from the random walk hypothesis. In this regard, those earlier KLSE studies in favour of EMH might have drawn incorrect inferences or even policy recommendations since they have implicitly disregarded the presence of non-linearity[1]. This concern is well directed as Lim *et al.* (2003a) and Lim and Tan (2003) provided convincing evidence that non-linearity plays a significant role in the underlying dynamics of the Malaysian stock market.

In the weak-form test of EMH, one has to be cautious when interpreting the results of linear and non-linear serial dependencies. There is no doubt that the conclusion of weak-form market efficiency can be made when the random walk hypothesis cannot be rejected by a robust test such as the Brock-Dechert-Scheinkman (BDS) test[2]. However, when the hypothesis is instead rejected due to the presence of certain dependency structures, it will be a strong statement to conclude that the market is inefficient. This was highlighted by Ko and Lee (1991: 224), "*If the random walk hypothesis holds, the weak form of the efficient market hypothesis must hold, but not vice versa. Thus, evidence supporting the random walk model is the evidence of market efficiency. But violation of the random walk model need not be evidence of market inefficiency in the weak form*". The deciding factor here is whether those detected patterns in the historical sequence of stock prices can be exploited by investors to earn abnormal rates of returns. To reiterate, though the evidence of linear and non-linear dependencies implies the potential of returns predictability, it has to be further demonstrated, in order to reject the weak-form EMH, that investors are able to profitably exploit those detected underlying patterns. For instance, Kok and Lee (1994) and Kok and Goh (1995) argued that though daily price series are found to be serially correlated in their respective studies, the magnitude of the correlations is not large enough for any mechanical trading rules to be devised for profitable investment timing. Hence, the presence of linear dependencies in their studies cannot be taken as evidence against the weak-form EMH. In contrast, the potential of predictability as suggested by the variance ratio test results in Lai *et al.* (2003) is verified by the significantly positive returns generated by the fixed length moving average (FMA) and variable length moving average (VMA) trading rules even in the presence of trading costs. Another excellent piece of work is provided by Ammermann and Patterson (2003), in which the authors found that the detected non-linear dependency structures are not persistence enough to allow improvements over the random walk for predicting stock returns. Rather, these dependencies show up at random intervals for a brief period of time but then disappear again before they can be exploited by investors.

---

[1] Liew *et al*. (2003) demonstrated that the conventional diagnostic tests are unable to identify the inadequacy of linear model for most of the Asian real exchange rates under study. In this case, using a mis-specified linear model will result in incorrect inferences and wrong clues in policy matters.

[2] The BDS test developed in Brock *et al*. (1987, 1996) has been proven to be quite powerful in detecting departures from i.i.d. behaviour in some Monte Carlo simulations (see, for example, Brock *et al*., 1991; Hsieh, 1991). In particular, the test has good power to detect at least four types of non-i.i.d. behaviour: non-stationarity, linear dependencies, non-linear stochastic process and non-linear deterministic process. Lim *et al*. (2003b) provided a literature review and brief discussion on the BDS test. The authors also applied the test to re-examine the random walk hypothesis in the Malaysian stock market.

The above discussion clearly shows that it is not sufficient to only uncover 'patterns' in the underlying DGP, but requires further verification on its predictability. One alternative approach[3] is to ensure that the detected patterns are persistent across time in order for them to have much benefit to investors (Ammermann and Patterson, 2003). To achieve this objective, the present study utilizes the windowed-test procedure of Hinich and Patterson (1995). The test is designed to detect episodes of transient serial dependencies within a data series, by breaking the full sample into smaller sub-samples or windows of data. In other words, this procedure examines whether the dependencies found in the full sample are in fact due to strong but episodic occurrences that appear only infrequently and fleetingly. Hinich and Patterson (1995), Brooks and Hinich (1998), Brooks *et al.* (2000) and Ammermann and Patterson (2003) have utilized this procedure to investigate the time series properties and stability of the underlying dynamics of financial data.

This study is further motivated by the recent empirical findings of episodic transient behaviour of dependencies in financial time series of developed markets. Brooks and Hinich (1998) found that the Sterling exchange rates are characterized by transient epochs of dependencies surrounded by long periods of white noise, suggesting that the serial dependency structures detected are not stable, but rather vary over time. Similar application to stock indices by the authors reveals the prevalence of these statistical features. In Ammermann and Patterson (2003), a closer examination via the windowed-testing procedure of Hinich and Patterson (1995) shows that the detected non-linear dependencies do not appear to be cross-temporally universal in that there are few brief periods in which the dependencies are very noticeable while other periods, in fact most of the time, the returns rather closely approximating a random walk. This means that the significant full sample results for non-linearity are actually triggered by the activity within a few relatively short "pockets" of highly non-linear data. It was suggested by the above two studies that these episodic transient behaviour are likely to be prevalent in many financial markets. Thus, it would be interesting to investigate whether the financial data of developing countries exhibit similar instability in the DGP. With this motivation, along with its profound implications on the weak-form EMH as discussed earlier, this study attempts to make a modest contribution to the current literature by broadening the existing evidence to include the emerging Malaysian stock market.

In the following section, this paper gives a brief description of the data and the methodology used in this study. Section III presents the empirical results as well as the analysis of the findings. Finally, concluding remarks are given at the end of the paper.

METHODOLOGY

The Data

This study utilizes the daily closing values of Kuala Lumpur Stock Exchange Composite Index (KLSE CI) for the sample period of 2 January 1990 to 30 June 2002. The price series obtained are used to compute a set of continuously compounded percentage returns for the KLSE CI, using the relationship:

$$r_t = 100 * \ln(P_t/P_{t-1}) \tag{1}$$

where P_t is the closing price on day t, and P_{t-1} the rate on the previous trading day.

Hinich and Patterson's Windowed-Test Procedure

In the windowed-test procedure of Hinich and Patterson (1995), a correlation portmanteau test similar to the Box-Pierce Q-statistic is developed for the detection of correlation or linear serial dependencies within a window. For detecting non-linear serial dependencies within a window, the procedure uses a bicorrelation portmanteau test, which can be considered as a time-domain analog of the Hinich bispectrum test statistic (Hinich, 1982). In applying these tests, the full sample is broken down into smaller sub-samples or windows of data. If the full data sample does exhibit significant linear or non-linear serial dependencies, but there are only a few smaller windows that are significant, then this suggests the data may instead be characterized by episodes of transient dependencies. In other words, it is the activity of these few windows that is actually driving the results of the overall sample. As demonstrated in the Monte Carlo simulations of Hinich and Patterson (1995), the test performed well even with small sample sizes.

---

[3] The conventional approach is to examine whether trading rules can generate abnormal rates of returns, net of all transactions costs, as adopted by Lai *et al.* (2003). However, Neely (1997: 29) cautioned that: "*The rule should be commonly used to reduce the problem of drawing false conclusions from data mining- a practice in which many different rules are tested until, purely by chance, some are found to be profitable on the data set. Negative test results are ignored, while positive results are published and taken to indicate that trading rule strategies can yield profits*".

In this section, we provide a brief description of the test statistics used in this windowed-test procedure[4]. Let the sequence $\{y(t)\}$ denote the sampled data process, where the time unit, t, is an integer. The test procedure employs non-overlapped data window, thus if n is the window length, then k-th window is $\{y(t_k), y(t_k+1),\ldots, y(t_k+n-1)\}$. The next non-overlapped window is $\{y(t_{k+1}), y(t_{k+1}+1),\ldots y(t_{k+1}+n-1)\}$, where $t_{k+1} = t_k+n$. The null hypothesis for each window is that $y\{t\}$ are realizations of a stationary pure noise process[5] that has zero bicovariance. The alternative hypothesis is that the process in the window is random with some non-zero correlations $C_{yy}(r) = \mathrm{E}[y(t)y(t+r)]$ or non-zero bicorrelations $C_{yyy}(r, s) = \mathrm{E}[y(t)y(t+r)y(t+s)]$ in the set $0 < r < s < L$, where L is the number of lags.

Define $Z(t)$ as the standardized observations obtained as follows:

$$Z(t) = \frac{y(t) - m_y}{s_y} \tag{2}$$

for each $t = 1, 2,\ldots, n$ where m_y and s_y are the sample mean and sample standard deviation of the window.

The sample correlation is:

$$C_{ZZ}(r) = (n-r)^{-\frac{1}{2}} \sum_{t=1}^{n-r} Z(t)Z(t+r) \tag{3}$$

The C statistic, which is developed for the detection of linear serial dependencies within a window, is defined as:

$$C = \sum_{r=1}^{L} [C_{ZZ}(r)]^2 \quad \sim \chi^2_{(L)} \tag{4}$$

The (r, s) sample bicorrelation is:

$$C_{ZZZ}(r,s) = (n-s)^{-1} \sum_{t=1}^{n-s} Z(t)Z(t+r)Z(t+s) \quad \text{for} \quad 0 \leq r \leq s \tag{5}$$

The H statistic, which is developed for the detection of non-linear serial dependencies within a window, is defined as:

$$H = \sum_{s=2}^{L} \sum_{r=1}^{s-1} G^2(r,s) \quad \sim \chi^2_{(L-1)(L/2)} \tag{6}$$

where $G(r,s) = (n-s)^{\frac{1}{2}} C_{ZZZ}(r,s)$

In both the C and H statistics, the number of lags L is specified as $L = n^b$ with $0 < b < 0.5$, where b is a parameter under the choice of the user. Based on the results of Monte Carlo simulations, Hinich and Patterson (1995) recommended the use of $b=0.4$ in order to maximize the power of the test while ensuring a valid approximation to the asymptotic theory.

A window is significant if either the C or H statistic rejects the null of pure noise at the specified threshold level. This study uses a threshold of 0.01. In this case, the chance of obtaining a false rejection of the null is approximately one out of every 100 windows. With such a low-level threshold, it would minimize the chance of obtaining false rejections of the null hypothesis indicating the presence of dependencies where these actually do not exist.

---

[4] Interested readers can refer Hinich and Patterson (1995) and Hinich (1996) for a full theoretical derivation of the test statistics and some Monte Carlo evidence regarding the size and power of the test statistics.

[5] A stationary time series is called pure-noise or pure white-noise if $y(n_1),\ldots, n_N$. A white noise time series, by contrast is one for which the autocovariance function is zero for all lags. Whiteness does not imply that $y(n)$ and $y(m)$ are independent for $m \neq n$ unless the series is Gaussian.

Another element that must be decided upon is the choice of the window length. In fact, there is no unique value for the window length. According to Brooks and Hinich (1998), the window length should be sufficiently long to provide adequate statistical power and yet short enough for the test to be able to pinpoint the arrival and disappearance of transient dependencies, which is the main purpose of using a windowed-test procedure. In this study, we followed the choice of Brooks and Hinich (1998) in which the data are split into a set of non-overlapping windows of 35 observations in length, approximately seven trading weeks. In fact, it was found that the choice of the window length does not alter much the results of both test statistics.

EMPIRICAL RESULTS

Table 1 provides summary statistics for the returns series in order to get a better view of some of the important statistical features. The means are quite small. The KLSE CI returns series exhibit some degree of positive or right-skewness. On the other hand, the distributions are highly leptokurtic, in which the tails of its distribution taper down to zero more gradually than do the tails of a normal distribution. Not surprisingly, given the non-zero skewness levels and excess kurtosis demonstrated within these series of returns, the Jarque-Bera (JB) test strongly rejects the null of normality.

Table 1: Summary statistics for KLSE CI Returns Series

	KLSE CI Returns Series
Sample Period	2/1/1990-30/6/2002
No. of observations	3259
Mean	0.007818
Median	0.000000
Maximum	20.81737
Minimum	-24.15339
Std deviation	1.679596
Skewness	0.457460
Kurtosis	38.02681
JB normality test statistic	166713.4
p-value	(0.000000)*

Note: * Denotes very small value

Table 2 presents the correlation (*C*) and bicorrelation (*H*) test statistics for the full data sets. If the *C* and *H* statistics are highly significant, it will then prompt us to examine whether these serial dependency structures are stable or instead their occurrences are episodic and transient in nature. The results in Table 2 reveal that both the *C* and *H* statistics are highly significant, with extremely small *p*-values[6]. This indicates the non-randomness of successive price changes in KLSE, with strong evidence of linear and non-linear serial dependencies within the KLSE CI returns series. The present results corroborate the findings of linear dependencies in Yong (1989, 1993) and Lai *et al.* (2003), and evidence of non-linearity reported by Lim *et al.* (2003a) and Lim and Tan (2003). This also provides some plausible explanation to the rejection of the random walk hypothesis by the BDS test in Lim *et al.* (2003b).

Table 2: *C* and *H* Statistics for KLSE CI Returns Series

	KLSE CI Returns Series
Sample Period	2/1/1990-30/6/2002
No. of observations	3259
No. of lags	25
No. of bicorrelations	300
p-value	
- *C* Statistic	0.0000*
- *H* Statistic	0.0000*

Note: * denotes extremely small *p*-value.

---

[6] Instead of reporting the *C* and *H* statistics as chi-square variates, the T23 program written by Hinich reports the statistics as *p*-values. Based on the appropriate chi square cumulative distribution value, the T23 program transforms the computed statistic to a *p*-value.

Subsequently, we examine whether the detected dependency structures in the full sample, both linear and non-linear, are in fact due to strong but episodic occurrences that appear only infrequently and fleetingly. Table 3 shows the results for the windowed testing, in which the data are split into a set of non-overlapping windows of 35 observations in length, approximately seven trading weeks. In this case, four lags are used in calculating both the C and H statistics. The fifth row in Table 3 shows the number of windows where the null of pure noise is rejected by the C statistic[7]. In parenthesis is the percentage of significant C windows. The results show that the null is rejected in six windows by the C statistic, which is equivalent to 6.45%. By using a threshold level of 0.01, we would expect the C statistic to reject 1% of the windows by random chance. However, the percentage of windows exhibiting significant linear serial dependencies is greater than the expected 1%. Similarly, the percentage of significant H windows is also larger than the 1% nominal threshold level, as displayed in the seventh row of the same table, suggesting that the rejection is not purely by chance.

Since both the C and H statistics are highly significant for the full data series as reported in Table 2, one would expect these serial dependencies to be persistent throughout the data or at least many more of the windows to exhibit strong serial dependencies. Instead, these significant test results in the full data series are reflected in only a relatively few windows. In other words, it is the activity of these few windows that is actually driving the results of the overall sample. Specifically, out of the total ninety three windows, only six (6.45%) exhibit significant linear serial dependencies and four (4.30%) exhibit non-linear serial dependencies. These results might be able to explain the mixed findings of those KLSE studies using standard methodologies and the KLSE CI data. It is possible that the serial correlation test, runs test and unit root tests employed in Barnes (1986), Saw and Tan (1989), Annuar *et al.* (1993) and Kok and Goh (1995) are unable to detect linear dependencies in these few windows. In contrast, the results of Lai *et al.* (2003) show that variance ratio test has higher power in detecting departure from the random walk hypothesis.

These episodic transient dependencies in the data indicate that the KLSE CI returns series are not stable, with the returns during most of the time periods move along at a close approximation to random walk, while during the remaining time periods (ten windows) they are characterized by highly significant linear and non-linear serial dependencies. The windowed-test procedure has an added advantage in that it permits a closer examination of the precise time periods during which these dependencies are occurring. Table 3 also reports these time periods, which are potentially useful for our future investigation into the causes of these detected episodic transient dependencies.

Table 3: Windowed-Test Results for KLSE CI Returns Series

	KLSE CI Returns Series
Total number of windows	93
No. of lags	4
No. of bicorrelations	6
Significant C windows	6 (6.45%)
Dates of significant C windows	29/5/1990-16/7/1990
	7/5/1991-24/6/1991
	13/8/1991-30/9/1991
	7/1/1992-24/2/1992
	21/7/1992-7/9/1992
	29/5/2001-16/7/2001
Significant H windows	4 (4.30%)
Dates of significant H windows	17/7/1990-3/9/1990
	5/3/1996-22/4/1996
	4/8/1998-21/9/1998
	4/9/2001-22/10/2001

CONCLUSIONS

This study utilizes the windowed-test procedure of Hinich and Patterson (1995) to examine the data generating process of KLSE CI returns series. Our econometrics results indicate that linear and non-linear dependencies play a significant role in the underlying dynamics of the returns series examined. However, these dependencies are not stable and persistent as they are episodic and transient in nature. Given the prevalence of these episodic transient dependencies across financial markets in the world, it would certainly be important to the field of finance and deserve the attention of researchers.

---

[7] In this study, the threshold level has been set at 0.01. The level of significance is the bootstrapped thresholds that correspond to 0.01.

At first glance, the evidence of linear and non-linear dependencies indicates departure from random walk and hence implies the potential of returns predictability. However, as discussed in the earlier section, in order to reject the weak-form EMH, one has to demonstrate that investors are able to profitably exploit these detected dependency structures. The episodic transient behaviour of these dependencies suggests that they are not stable and persistent across time for investors to benefit from it. As illustrated in Table 3, these significant dependencies show up at random intervals for a brief period of time but then disappear again before they can be exploited by investors. The results, taken as a whole, do not constitute strong evidence against the weak-form EMH as the returns series move along at a close approximation to random walk for most of the time periods.

It would be interesting to investigate the events that triggered these episodic transient dependencies in the data. This is possible because the windowed-test procedure of Hinich and Patterson (1995) permits a closer examination of the precise time periods during which these dependencies, linear and non-linear, are occurring, as reported in Table 3. For instance, in the work of Ammermann and Patterson (2003), the linear dependencies are found to be directly attributable to changes in the Taiwan Stock Exchange's price limits that were made during 1987 and 1988. Brooks *et al.* (2000) found that the non-linear dependency structures in their data are due to widespread upsets in the currency markets and a change in US accounting procedures. This line of inquiry is certainly worth investigating and will be included in future research agenda.

Corporate Governance Practice of Labuan Offshore Companies:
A Comparative Study between Offshore Banks and Insurance Companies

ABSTRACT

A much better understanding of corporate governance practices in financial institutions is of particular concern to investors and regulators. From the perspective of agency and institution, corporate governance addresses policies and procedures to protect shareholders' interest. The aim of this study is to analyze the influence and relationship of factors towards the corporate governance practices of Labuan offshore companies for the year of 2003. With offshore banks and insurance companies as the focus, we tested several hypotheses using survey data. Despite a relatively small sample size, only one corporate governance attribute namely the roles of the executive and non-executive directors was found to have a significant influence towards the company's accountability for offshore banks. However, for offshore insurance companies, corporate disclosure rules and regulations; director's qualifications and experiences; and audit committee effectiveness were found to be the key factors to improve the current corporate governance regime. Overall, these findings suggest that effective corporate governance is crucial to a firm's performance.

_____

INTRODUCTION

> *"Corporate governance is the process and structure used to direct and manage the*
> *business and affairs of the company towards enhancing business prosperity and*
> *corporate accountability with the ultimate objective of realizing long term shareholder*
> *value, whilst taking into account the interests of other stakeholders."*
> *– Malaysian Code on Corporate Governance, March 2000.*

In today's world, corporate governance is at the core of the process of directing a company. Davies (1999) revealed that it provides the leadership, values together with checks and balances needed to ensure survival. An important point here is that good governance is an aid to effectiveness which is not to shackle any company but to harness and harmonize them in the achievement of its goals. The 1997 Asian financial crisis for example, have created pressure to the market players namely the governments, corporations and financial institutions to improve their performance through greater commitment. As mentioned by Naik (1997), financial markets and institutions, play an important social and economic role that has a profound influence on the quality of investment decisions and the well being of the general economy. Thus the shareholder value and its relationship with business performance and corporate governance have become a major concern for today's companies.

In this paper, we examine the relationship of attributes of effective corporate governance practice towards Public Listed Company's (PLC) accountability focusing on two financial institutions; the offshore banks and insurance companies situated in Labuan. Elements to be studied from the managerial level perspective comprise of rules and regulations disclosure practice, roles and responsibilities, academic and experience background of directors, auditors' roles, audit committee effectiveness and the effect of nomination and remuneration committee. We will also discuss the impact of authorities' role and further improvement on this subject.

REVIEW OF THE LITERATURE

Sir Adrian Cadbury once notes that the foundations of good governance are disclosure or transparency and the presence of independent outsiders, which in the long run may form the basis for strong public confidence in any institution. Together it builds up the ethical standards for a lasting governance system.

Corporate governance is an increasingly popular topic among directors, institutional investors, legislators and regulators, managers and academics. The systems help determine how decisions are made about spending resources on building organizational capabilities, and how management and employees are evaluated and compensated. It is also able to recognize the inherent conflict among objectives of owner-shareholders and managers, and establish institutions, policies and procedures to protect shareholders' interests (McCarthy & Puffer, 2002a). However in the last few years, most participants in the corporate governance debates have discredited that corporations should be run in the interests of all of the stakeholders, rather than just for the shareholders (Blair, 1995). Referring Hansmann and Kraakman (2000) notion of 'The end of History of Corporate Law', they argue that a global consensus has now emerged when 'corporate managers should act exclusively in the economic interest of shareholders' and as a result, all jurisdictions will inevitably move towards the outsider model of corporate governance'.

Banks, corporation and government have close relationships in many Asian countries. Claims that corporate governance system (mainly in the financial industry) is undergoing convergence have intensified in the wake of the Asian crisis. Hamid Mehran of Federal Reserve Bank of New York highlighted that during times of crisis, banks provide liquidity and maintain deposits supported by government insurance. Scholars too have argued that large, short-term internal and external debts and openness of many East Asian economies, constrain the monetary and exchange rate policies. It is also due to inappropriate macroeconomic policy during the 1990s that have been made worse by inefficient management of initial depreciation in 1997 (Corsetti et al., 1998). In order for these countries to resume sustained high growth, they need to improve corporate governance (McKinsey, 1998). Thus, changing corporate governance practice, is a long-term process and may have to establish fundamental cultural and institutional changes if needed (Iskander et al., 1999). For example, governments of East Asian crisis countries are becoming owners of substantial assets (through takeovers of insolvent banks and asset-management companies) and consolidation of the banking industry have gain extra attention to maximize the shareholder wealth. Further reported by McKinsey Quarterly (2004), in Thailand, various firms inclusive of asset-management and life insurance companies have formed the Institutional Investor Alliance while in Singapore, the Securities Investors Association works together with companies to promote better corporate governance.

ATTRIBUTES OF CORPORATE GOVERNANCE PRACTICE

Although the concept of accountability, transparency, responsibility, disclosure, honesty and integrity are all closely related with corporate governance practice, it however only relies on the company's compliance rather than enforcement by way of law (Black & Kraakman, 1996). According to Fama and Jensen (1983), both internal and external governance elements are designed to minimise divergence, which arise from the separation of ownership and decision control.

Rules and regulations disclosure practice: To improve transparency by increasing disclosure requirements and auditing practices, most Asian countries (mainly Malaysia, China, Philippines, Singapore and Thailand) are gradually harmonizing its national financial-reporting standards with international standards. These countries are now requiring quarterly reporting to enhance transparency to all the parties involved. Management, the agent whom shareholders entrusted control over a portion of their resources (Watts & Zimmerman, 1979), have incentives to disclose favorable and also unfavorable information to the shareholders. Information disclosure besides reporting financial statement status may also include articulation of long-term strategy, non-financial indicators, and leading indicators and future profits (Kee & Pillay, 2002). One way to convey relevant information is to produce quality Corporate Annual Reports (CARS); a communication tool, which have direct influence towards accountability (Razman & Iskandar, 2002). To date, CARS have been constantly updated due to rapid changing demands from numerous regulatory bodies and to increase its reliability towards the public.

Director's roles, responsibilities, qualifications and experiences: The reformation of corporate practice will involve issues such as the composition of boards, how board members are appointed, how many truly independent board members are appointed, and how boards function. These issues are particularly crucial to address due to the domination of many boards by strong owner-managers (Fung, 2001). Most companies from various industries have boards on which all or a majority of non-executive directors are independent. The larger the company's size, the more likely it may have three or more independent non-executives. Although director's delegate most management and control function to the company's top management, they must have ultimate control over top management, which covers monitoring important decisions. This is further explained by acknowledging an important factor in creating a board, which compose both management (inside) and non-management (outside) members to support the board's effectiveness in monitoring management (Fama & Jensen 1983; Kosnik, 1987; Mallette & Hogler 1995; Beasley, 1996). Information advantages because of internal mutual monitoring will assist the board in decision-making, thus it is natural for the most influential board

members to be the internal managers. The inclusion of non-management board of directors however will increase the ability to prevent financial statement fraud.

Auditors' roles: A study by Abdullah and Iskandar (2003) has demonstrated that independence and activeness, plays an important role when selecting good auditors. It is crucial since the right decision-making will enhance a corporation's economic status and resources. Other studies also conclude that auditor's competency and expertise, audit committee member's financial literacy and director's position in other companies may also influence the choices of auditors (Kalbers, et al., 1993; Braiotta, 1994; Abdullah & Al-Murisi, 1997; DeZoort 1998; Abbot & Parker, 2000). As reported by earlier studies (Kunitake, 1981; Eichenseher & Shields, 1985; Cottell & Rankin, 1988; Apostolou & Jeffods, 1990; Craswell et al. 1995), the right selection of external auditors will assist better financial reporting disclosure and thus improve the audit service quality.

Audit committee effectiveness: Audit committee is a voluntary monitoring mechanism employed in a high stake agency cost situations with an objective to improve the information flow quality between both principle and agent (Pincus et al. 1989). They have become a vital link between external and internal auditors when reviewing the effectiveness of any company's internal controls thus increase the corporate accountability framework (Braiotta, 1994). Several prior researches have applied agency theory to examine the audit committee's role in monitoring management's selection of significant accounting policies that affects financial reporting reliability (Campbell et al. 1982; Mc Mullen 1992; Collier 1993; Henry et al. 1994). Results of some previous studies report the expectation that the board of director's composition (Watts, 1997; and Beasley, 1996) and the presence of audit committee (Campbell, 1982; Brown and Sarah, 1990; Henry et al., 1994) were connected to the board's effectiveness at reducing financial statement fraud and agency costs. Thus their presence increases public confidence on the credibility of financial statement disclosure.

Nomination & remuneration committee: Although the nomination and remuneration committee is not a must, it could be a good practice in particular to make recommendation on all new board appointments (OECD, 1998). However, exception can be given to board with smaller size. To prevent moral hazards, the Cadbury Committee and the Greenbury Committee have strongly emphasized that majority of the committee should be non-executive directors although not necessarily independent (Parkinson & Kelly, 1999).

DATA AND METHODOLOGY

The Flemings Research (Global Emerging Markets, June, 1998) develops measure of corporate governance based on information disclosure, transparency of ownership structures, management and special groups' interest, adequacy of the legal system, board of company's independence, minority shareholder rights and enforcement of corporate standards. This measurement is based on a 5-point Likert scale, which tries to capture the extent of shareholder rights in practice. McCarthy and Puffer (2003) however, suggest a framework of corporate governance, which depicts four elements of environment (economic, technology, legal/political and social/cultural) and three-stakeholder group (internal, external and peripheral). Their entire framework is viewed as an interrelated system rather by individual role. The accountability of corporate governance practices constantly evolves to meet changing conditions thus there is no single universal model or a final structure of corporate governance that any country or corporation should emulate. Therefore in this study, the relationships between the attributes of corporate governance are diagrammed in Figure 1.

- DISCLOSE: Rules and regulations disclosure practice
- ROLES: Roles and responsibilities

→ Labuan Off-Shore Banks and Insurance Companies' Accountability

Figure 1: Theoretical Framework
Research context: Labuan International Offshore Financial Centre (IOFC)

Labuan IOFC, an offshore centre that facilitates offshore financial services activities is rapidly expanding its cross-border transactions and performance with 4,065 offshore companies in operation. Today, the updated figure represents more than 70 companies with Labuan Offshore Financial Services Authority (LOFSA) assistance under the auspices of Bank Negara Malaysia.

Due to the encouraging economic environment in 2003, the offshore banking industry has recorded a profit of USD1.3 million which is a turnaround value from a loss of USD14,000 in the previous year. The offshore insurance industry also has been showing an overall growth of 4.0% in 2003 with 13 new licenses been registered. Indication by the Bank Negara Malaysia have proved that the total growth for the industry has increased by 30.4% to USD914 million (2003), compared with only USD701 million 2002. Table 1 and 2 below indicate important statistics to both the offshore bank and insurance industry.

Table 1: Offshore Banks – Key Data

	As at end of			2002	2003
	2001	2002	2003	%	Change
Number of Banks Licensed	54	54	56	0.0	3.7
Number of Banks in Operations	54	50	53	(7.4)	6.0
Total Deposits (USD million)	3,657.4	5,865.6	3,702.0	60.4	(36.9)
Malaysian Offshore Banks	1,545.1	3,919.0	2,308.5	153.6	(41.1)
Foreign Offshore Banks	2,112.3	1,946.6	1,393.5	(7.8)	(28.4)

Arising from the needs to improve corporate governance practice system and structure, the Labuan Offshore Securities Industry (Amendments) Act 2003 (LOSIA) and Anti-Money Laundering (Bank Negara Annual Report, 2003) were recently established to enhance the regulatory and supervisory practice in Labuan IOFC. Thus, Labuan IOFC was chosen as the research focus for this empirical study with the intention to better understand the relationship between corporate governance attributes and firm's accountability.

Research design: In this study, we distributed and analyzed primary data using surveys on a seven point Likert scale. Several questions were adopted from the study conducted by Bursa Malaysia (formerly KLSE)/Pricewaterhouse Coopers and earlier study by Wafa et al. (2001). The primary criteria for selecting respondents to participate are (1) current involvement with either bank or insurance business at managerial level, (2) have gone through formal education and/or professional training and (3) have a number of years of experience in accounts, corporate finance and/or legal sectors. We also assume that the respondents have basic knowledge on corporate governance practices. The Cronbach alpha for the variables obtained, ranged from 0.68 to 0.96 that indicate acceptable reliability.

EMPIRICAL RESULTS

Completed surveys were collected from 25 offshore banks and 12 insurance companies yielding an overall response rate of thirty seven percent from 100 firms. Most of the offshore bank respondents were more than 34 years of age (76%) compared to 66 percent in the offshore insurance. A majority of the respondents for both banks (66%) and insurance companies (58.3%) have more than 10 years of working experience. Grouping them according to professional training area, for offshore banks the respondent focuses in accounting (28%), business administration (20%), finance (20%), law (16%). Offshore insurance recorded 16.7 percent in accounting, 8.3 percent in business administration, insurance and law respectively. For offshore banks the proportion of respondents working for companies in the Public Listed Company (PLC) category was 40 percent. Insurance companies however recorded a slightly higher percentage (i.e. 50 percent).

The descriptive statistics for this study are shown in both Table 3 (offshore banks) and Table 4 (offshore insurance companies).

** *p < 0.01*
 * *p < 0.05*

The correlation analysis results for the offshore banks and insurance companies indicate that the overall rules and regulations disclosure mean values are 5.56 and 5.08 respectively. The findings also indicate that the executive and non-executive directors are fully aware of their roles and responsibilities with mean showing 5.18 for banks and a slightly lower for insurance at 4.92. A more detailed analysis of the second variable too provides evidence that the respondents agree with non-executive directors having served a useful purpose as discussion confidants. From both perspectives, the respondents further acknowledge the importance of executive directors' qualification and experience with mean reflected at 5.57 and 5.17 accordingly. The roles of external and internal auditors score 4.75 for insurance companies while banks record a slightly higher value at 5.46 for the same analysis. Table 3 and 4 also display that the audit committee are perceived to have effectively discharged their duties and responsibilities with means of 5.02 and 4.96 respective to Labuan offshore banks and insurance companies. This finding is also consistent with the perception given by the respondents, which states that a majority of the audit committee members should be non-executive directors. Although the nomination and remuneration committees are quite rare in most companies, the mean values are equivalent to 4.64 and 4.71 for banks and insurance companies, which still proves the importance of establishing this committee. Comprehensively, corporate governance standards are perceived to be quite highly related with the companies' accountability. The overall results indicate offshore banks with a mean of 5.24 while offshore insurance companies recorded 4.93, which is slightly above midpoint.

Table 3 also shows that there were quite large and significant positive inter-correlations between the tested variables for offshore banks. Insurance companies however, identify a slightly lower number of positive inter-correlation amongst variables at significant level of 1 percent or 5 percent. Remarkably in both tables, the business sectors recorded similar results on identifying five of the six variables (with the exception of the Nomination and Remuneration Committee) to be significantly correlated with the companies' accountability. These results however are quite conflicting with values from the regression analysis in Table 5.

Table 5 Regression analysis on Corporate Governance Practice – The Step-Wise Method

Variable	Bank				Insurance			
	Beta	t-value	Sig T	VIF	Beta	t-value	Sig T	VIF
DISCLOSE	0.15	0.63	0.534	3.67	0.41	*6.09*	*0.000*	2.25
QUALIFY	0.04	0.19	0.854	2.35	0.50	*6.72*	*0.000*	1.34
AUDITCOM	-0.10	-0.63	0.535	1.74	0.37	*4.14*	*0.003*	2.27
ROLES	0.34	*2.86*	*0.009*	1.30	-0.21	-2.24	0.060	4.91
AUDIT	0.01	0.06	0.951	1.72	-0.13	-1.22	0.262	4.34
NOMREM	-0.04	-0.22	0.825	1.93	-0.02	-0.42	0.688	1.29
R^2	0.68				0.98			
Adjusted R^2	0.65				0.97			
F-Statistics	22.91				34.82			
Sig F	0.00				0.00			
Condition Index	14.87				21.985			
Durbin Watson	2.74				1.66			

 In Table 5 through the application of step-wise regression, all the independent variables are significant as indicated by the F-values for both the offshore banks and insurance companies. From the study, 68% of the banks dependent variable (accountability of offshore banks) as reflected by the R^2, can be explained by the independent variables. The analysis of insurance companies anyway, recorded a much higher value at 98%. In sum, the accountability of both sectors being influenced by the independent variables or at least one of the independent variables is highly significant. The study shows no serial correlation evidence as the Durbin Watson statistics is within acceptable range and both Condition Index estimates are below the rule-of –thumb cutoff of 30. Here, we also investigate any potential multicollinearity problems by examining the variance inflation factors (VIFs) and the results from Table 4 are clear for the sectors where VIF values are also well below the cutoff point. Thus we can conclude that the regression estimates for the variables were not adversely affected by the presence of multicollinearity problems.

As described in earlier paragraph, by comparing the actual five variables (through correlation analysis) that are significantly related towards the accountability of Labuan offshore banks and insurance companies, the regression analysis results in Table 5 however, indicates that for offshore banks only one was significant that is the roles and responsibilities of the executive and non-executive directors (0.34). Insurance companies on the other hand recorded three variables which were found significant namely rules and regulation disclosure practice (0.41); academic background and experience of executive and non-executive directors (0.50); and audit committee effectiveness (0.37).

DISCUSSION AND IMPLICATIONS

Rules and regulations disclosure practice

The regression score in Table 5 showing insignificant result of the offshore banks' rules and regulations disclosure practice could be attributed to the perception of banks that they are free from detection and this could be a sign of lack of enforcement in the Labuan IOFC. For instance, upon issuance of banking operation license, the offshore banks should abide to certain rules by LOFSA such as to comply with prudential and reporting requirements. However in this case, the respondents perceived that the enforcement is not sufficient. This differs from the result for insurance companies, which show significant relationship between disclosure practices towards the firm's accountability. Thus, the finding is more adequately adhered to theories supporting disclosure actions. For this entity, the respondents confirm that insurance companies have disclosed enough information especially matters regarding directors' dealing and business transactions.

Nevertheless in any situation, both banks and insurance companies ought to conduct business with sound principles and due diligence. This can be achieved by maintaining adequate and proper records of financial statement, statistics and information (LOFSA, 2001). Mitton (2002) found that firms with higher disclosure quality, greater transparency and corporate focus will experience better stock price especially during economic crisis. Recalling Razman and Iskandar (2002), an alternative way of conveying relevant information is to produce quality Corporate Annual Reports (CARS); a communication tool, which have been proven to have a direct relationship with accountability.

Roles and responsibilities (executive and non-executive directors)

Focusing on offshore banks' operation, the findings of this study are consistent with Demsetz (1995), who highlights that the larger and more complex an organization, the more is demanded of the top management. Furthermore, the value of written corporate governance guidelines or framework is becoming more apparent to boards in bigger firms today although the production of such a "board constitution" is in itself a major governance task. The findings related to offshore bank is also consistent with Brook et al. (2000), who suggest that board ownership particularly outside directors can play an important role in effective corporate governance. It can also be described by the facts that for offshore banks, prior written approval from LOFSA must be obtained for the appointment of a controller or director. This justifies and strengthens the significant role played by this attribute towards offshore banks' accountability. As for insurance companies, the insignificant value could be its directors' roles and responsibilities are not specifically stated (particularly the non-executive directors), which may lack meaning and practicality. Moreover, because of its smaller entity, the directors may also only act as fiduciaries to the firms' strategic operations (Kang & Sorensen, 1999).

Academic background and experiences

Director's expertise can often be enhanced through participation in a firm's governance structure for instance by serving on the board of directors, observing company's operation and contributes toward strategic decisions. Owners with strong qualifications and relevant experience are likely to incorporate well-informed discussion with the managers (Beasley, 1996). However, no significant relationship is found between the importance placed on the offshore banks directors' academic background and experiences, and the assessed offshore banks' accountability. In actual fact, usually the appointed directors are assisted by senior and professional management team during its day-to-day operations (Fama & Jensen, 1983; Wafa et al, 2001). Different conclusion was obtained for the offshore insurance, which shows a significant result. The reason is, offshore insurance companies are more restricted to LOFSA's rigorous prior approval requirements and standards (LOFSA, 2001). The steps taken are vital to guarantee the best selection of qualified, fit and proper directors. Besides that, due to its smaller size compared to offshore banks, the daily business routine and transaction are normally being observed individually by the appointed directors (note: at least one director resident in Labuan).

Auditors' roles (internal and external)

Auditors should realize its role to have proper reporting and disclosure particularly on all accounting procedures carried out by the offshore companies. However, the regression analysis indicates that both offshore banks and insurance companies have similar insignificant relationship of the attribute towards the accountability level. This explains that the internal and external auditors have been regarded to not perform their roles independently and in accordance with the statutory and professional requirement. Thus, discharging their duties and responsibilities less effectively. One reason, which perhaps influence this peripheral is the respondents' perceived feelings that the appointed internal auditors (whom at the same time are also the company's employees) and external auditors may provide non-audit services such as book keeping to their existing clients. For this reason, any accuracy on financial reporting and disclosure practice may fall far short of its main objectives.

Audit committee effectiveness

Audit committee is a necessary component of the financial reporting process and serves to deter fraudulent financial reporting thus enhancing more reliable information to be disclosed to the shareholder. Another function of audit committee is to provide private access to the directors for auditors (external and internal) if critical matters cannot be properly resolved through normal channels (Collier, 1993). Significant relationship between audit committee effectiveness and the accountability of offshore insurance companies justifies the respondents' agreement that the audit committees have efficiently discharged their duties and responsibilities.

However, conflicting result in Table 5 indicates no significant relationships were found between audit committee effectiveness towards the offshore banks' accountability. The answer to this scenario may be focused on the normal practice of the committee composition of non-executive directors. Wafa et al. (2001) in their earlier study have underlined one important justification on this matter; selection of the audit committee members may perhaps be done on the basis of being 'old-boys' which shows that the selections were not based on expected benefits and contributions. Hence jeopardizing the non-executives underlying principle; 'independent of management' and 'free from any business or other relationship that may materially interfere with the exercise of independent judgment' (Cadbury Committee).

Nomination and remuneration committee

Most firms seldom establish nomination and remuneration committee, thus the respondents can gather insufficient knowledge about it. This may perhaps justify why the nomination and remuneration committee is insignificant towards the accountability for both the offshore banks and insurance companies. The findings are consistent with Wafa et al. (2001) in their study on Malaysia PLCs' accountability. Even though the committees are quite rare or under utilized, earlier correlation analysis results in Table 3 and 4 show that the mean statistical values are slightly above midpoint. This justify why most respondents agree that the committee can be a good mechanism to ascertain that the companies' operations will be in better shape thus enhancing the overall performance. Hence, both industries should consider the recommendation made by the Cadbury Committee, the Greenbury Committee and the Hampel Committee that highlights the outstanding roles by above-mentioned committee to ensure transparency in the appointment of directors and fair determination of directors' salaries.

Overall, what is clear is that although the findings are tentative due to the small sample size, the study still supports future reformation and calls to enhance the current corporate governance regime in Labuan IOFC, particularly the offshore banks and insurance companies.

CONCLUSIONS

As a general guideline, both offshore banks and insurance companies must subscribe to safeguards and comply with standards by the relevant authority for instance management control system and adequacy of capital (LOFSA, 2001). For instance, certain actions including change of business plan must first be approved by LOFSA. Hence, the challenge lies with the policymaker (under the auspices of the Central Bank) to exercise comprehensive reform with equitable burden sharing among external participants (borrowers, equity holders, creditors and government) and internal parties (shareholders and workers). This is vital to restore confidence in the offshore financial system and positively lead to a more competitive financial and corporate system. This reduces default risk and minimizes the chances of a crisis.

 Shareholder value; strategic improvement; director activism; board independence; management partnership; shared decision-making; evaluation and improvement; these elements have been identified as the benefits to be gained from an improved corporate governance regime a practice. A lack of information is a huge issue and the board must really encourage the management to bring forward solid information especially on the strategic positioning of both offshore banks and insurance companies. In return the shareholder's value will definitely maximize if each and every director were well informed and work well. Corporate governance practices vary and will continue to vary across nations and cultures. Furthermore, it may also be different as a function of ownership structures, business circumstances, competitive conditions, company's life cycle and other factors (McCarthy & Puffer, 2003). All institutions need an improved framework of clear governance; comprising missions to be accomplished stated with clear rules and authorized conventions in order to guide its accomplishment. Hence throughout the years of awakening economy, corporate governance is no longer optional for any institutions – it is now a vital issue.

Corporate governance arrangements influence the efficiency use of society's resources and the firm's ability to create new wealth. It should also take into consideration the risk, rewards, incentives and motivations facing other stakeholders. As mentioned by Blair (1995), contractual arrangements and governance systems should be devised to assign control rights, rewards and responsibilities to the appropriate stakeholders – the parties that contribute specialized inputs to the company. For the sake of shareholders wealth, one notion is crucial; the better a firm's performance and control, the less severe the agency problems.

ABSTRACT

This study is trying to investigate major factors driving e-commerce adoption, and assess the organizational readiness for Malaysian companies operating in FIZ (Free Industrial Zone) in the state of Penang and Kedah. This study used structured questionnaires and a purposive judgmental sampling method in getting responses from IT managers or decision-makers on e-commerce initiative. Dependent variable is the organization readiness level in adopting e-commerce strategy and independent variables are online competitiveness, customer relationship management and value chain management. This study shows that Malaysian companies are lagging in e-commerce initiative compared to American companies, but Malaysian companies are on par with European and East Asian companies. It reflects the general views that e-commerce is "American Originated" technology and American companies have an edge in adopting this new and enabling technology to enhance their global competitiveness. The Malaysian companies have been proactively evaluating and embarking on IT projects to enhance their international competitiveness and they are on par with European and East Asian companies in e-commerce initiative. This study shows Online Competitiveness, Customer Relationship Management and Value Chain Management are affecting decision on e-commerce initiative. The results of this research will also serve as an initial feedback to Malaysian authorities to step up their efforts in promoting IT awareness, and adopting new and enabling technologies in Malaysian companies. It is also hoped that this study can provide a guideline for Malaysian companies in evaluating and formulating effective strategies and policies into e-commerce in this information age.

INTRODUCTION

Consider what tasks the company has to perform when an employee wants to buy something, for example, a filing cabinet. First the employee generates a request for the filing cabinet, including some specifications (four drawer vs five-drawer, with lock vs no lock), and passes this request on through an approval process involving one or more managers, depending on the cost. That request finally makes it over to the purchasing department, where someone has to check through the office supply catalogs to select an appropriate model and supplier. Assume the company doesn't have a single preferred supplier for office supplies, so the purchasing agent has to check more than one catalog and call the suppliers to determine the availability of the filing cabinet. Once the supplier is selected, the agent can issue a purchase order, and either fax or mail it to supplier.

Once the order has been received, the supplier verifies the credit and sales history of the ordering company, checks the warehouse for inventory, and finds out when shipper can pick up the cabinet from the warehouse and deliver it to the appropriate location. Satisfied with the item can be delivered within the time requested, the supplier creates a shipping order, notifies the warehouse, and creates an invoices for the filing cabinet. The invoice gets mailed, the filing cabinet gets delivered, and somewhere along the way, your company pays the bill for the cabinet.

Now consider how this might have been done using electronic commerce. The employee would visit the Web site of either the distributor or the manufacturer, and select the appropriate filing cabinet by matching the needs (colour, number of drawer, lock, size) with the data in an online catalog. The employee would then use electronic mail to send a digital request (perhaps appending the Web page of the selected product) to the manager for approval. Once approved, the manager would simply use e-mail to forward the request to purchasing. Purchasing could then copy the necessary information into their order database, and send an electronic order to the supplier, via EDI or other form, also using e-mail.

When the supplier receives the order, a computer program might automatically insert the order into a database of pending orders, check inventory at the warehouse, check your company's credit status, and earmark the item for delivery. The same program might then pass a shipping order electronically to appropriate warehouse and create an invoice. If a shipping agent is used, the warehouse would notify the shipper via e-mail. Once the filing

cabinet was received, accounts payable would instruct the bank, via e-mail, to transfer the appropriate funds to the supplier.

With electronic commerce, everything starts out and stays digital; only different applications are needed to transfer and process the data as it winds its way through the order process. Imagine how much more efficient this process would be if you were able to obtain all the information you needed right at your fingertips, and also make your purchases, all using one medium.

RESEARCH PROBLEM

The decision makers particularly the chief executive officers and chief financial officers in most organizations have difficulty in evaluating and adopting e-commerce strategy. In today's 'Networked Economy', where individuals and companies worldwide are being electronically linked, business rules keep changing and companies have to respond fast to changes to survive. Marketplace is changing every second at an increasing pace. E-commerce is increasingly crucial to business success, but implementing it successfully requires a broad understanding of technology, law, policy, and business processes. There are many factors affecting decision-making in adopting of E-commerce, the decision is complicated by the pace the Internet changes the business rules in the globalization age.

RESEARCH OBJECTIVES

Research in e-commerce in Malaysia is very limited and not widely published. This research is intended to study e-commerce initiatives for manufacturing companies operating in Free Industrial Zone (FIZ) in the state of Kedah and Penang. Specifically, the study is intended:
1. To investigate whether Malaysian companies are lagging in adopting e-commerce strategy compared to American, European and East Asian companies.
2. To study major factors driving decision making to adopt e-commerce strategy.

LITERATURE REVIEW

There are a variety of definitions of "electronic commerce" (e-commerce) in the literature. It has been defined as a combination of technologies (Electronic Commerce World Institute, 1996), as a business methodology (Kalakota & Whinston, 1996) and as business over networks and computers (Haynes, 1995).

Oracle Inc. defines e-commerce as a dynamic set of technologies, applications, and business processes that link enterprises, consumers, and communities through electronic transactions and the electronic exchange of goods, services and information (Internet Commerce, 1999).

For some time now, large business enterprises have used electronic commerce to conduct their business-to-business transactions. Electronic data interchange (EDI) on private networks began in the 1960s, and banks have been using dedicated networks for electronic fund transfer (EFT) almost as long. Recently, however, with the increased awareness and popularity of the Internet, electronic commerce has come to encompass individual consumers as well as business of all sizes (Kosiur, 1997).

The Internet is already changing the way that many companies conduct their business. As that influence grows, and more companies use the Internet, the possibilities for conducting business-to-business commerce on the Internet will expand greatly, and become more of a routine part of commerce than it is today.

To many, electronic commerce is defined as the buying and selling of products and services over the Internet, but there are many more aspects to it. From its inception, electronic commerce has included the handling of purchase transactions and funds transfers over computer networks. It is now grown to include the buying and selling of new commodities such as electronic information.

Over the past few years, both the press and business community have increased their focus on electronic commerce involving the consumer. Meanwhile business-to-business electronic commerce is rolling along, stronger than even ever. The Internet has also given business-to-business electronic commerce a boost – in some cases, smaller companies are now discovering that they can conduct business on line, just like their larger counterparts. And business of all sizes are finding that they can take advantage of the Internet to lower cost of electronic commerce – either by replacing other networks, or by using the Internet.

The move for business to digitize information isn't new – it's been going on for more than a decade, and continue to increase as personal computers become standard business equipment for more and more corporations. What is making a notable difference to businesses is that a significant synergy has formed between the use of digital information, computerized business practices, and the Internet. This synergy is what enables electronic commerce.

Forces Driving/Enabling E-Commerce

A study conducted by Anderson Consulting (1999) shows that there are four forces, as depicted in Figure 1, which drives or enables e-commerce, namely, business value, technology infrastructure, customer value and cooperative regulatory environment. Anderson Consulting predicts the electronic economy will overtake the traditional industrial economy by year 2003 (Anderson Consulting, 1999).

A reasonably favorable deregulatory environment increases the competitive tempo, which encourages businesses to seek means to obtain or retain a competitive advantage. Technology offers businesses new opportunities to enhance value to its customers, increase its efficiency and extend its reach. Consumers respond to the increased value by favoring these leading businesses. Thus rewarded, these businesses reward the technology providers with additional purchases. Consumers also favor governments trade liberalization, which has permitted and encouraged new value streams. Each circle of activity has been reinforcing the others (Anderson Consulting, 1999).

Figure 1: Four Forces Of Inevitability

Source: http://www.ac.com/ecommerce/ecom_what_is.html

In another study, conducted by a management consulting firm A.T. Kearney, sought the views of CEOs and senior business executives at 213 companies in 11 industries in more than 20 countries. The study shows nine out of 10 cited information technology (IT) as critical in every way or very important for their businesses' future success. One-third cited the use of new technologies as the top critical success factor for the future. 58% identified loss of competitive advantage as the main consequence of not keeping pace with IT (Saia, 1999). Information technology and Internet linkage are widely seen as the catalyst to propel the electronic commerce into every aspects of domestic and international trade.

Online Competitiveness

Whether leading the charge or tagging along one step at a time, companies today are moving inevitably towards a new commercial world order. Fundamental methods by which business is conducted will be forever changed as organizations use technology to link enterprises, consumers, and communities through electronic transactions and the electronic exchange of goods, services and information. "The Internet economy will have the same impact on society that the industrial revolution had 300 years ago", says John Chambers, the CEO of Cisco Systems (Internet Commerce, 1999).

In e-Commerce, coordination can be achieved virtually, at low cost. Whole supply chains can be forged quickly and connected through desktops. And whether the seller is really in Boston, its "warehouse" a totally different company in Topeka, and the payment processor still another firm in Bangladesh are considerations largely irrelevant to consumers as long as their expectations for quality, price and service are met. (Melnicoff, 1999)

Porter (1994) reported efficiencies generated by online commercial efforts on marketing on Web results in "10 times as many units [sold] with 1/10 the advertising budget". It is about one-fourth less costly to perform direct marketing through the Net than through conventional channels (Verity & Carey, 1994). This fact becomes

especially critical in the face of shortening technology and product life cycles and increasing technological complexity in the business arena of the globalization age. Using SunSolve Online, Sun Microsystems has save over US$ 4 millions in Frequently Asked Questions (FAQs), since Sun "reengineered information processing around the WWW" (Neece, 1995).

Web sites are available on demand twenty-four hours a day. The interactive nature of the Internet can be used by marketers to hold the attention of the customer, by engaging him or her in an asynchronous "dialogue" that occurs at both parties' convenience. This capability of the medium offers unprecedented opportunities to tailor communications precisely to individual customers, allowing them to request as much information as desired. Further, it allows the marketer to obtain relevant information from customers for the purpose of serving them more effectively in the future.

Value Chain Management

Communications and information technologies often make it more effective and less expensive to collaborate with outsiders than to own all the resources associated with your business. Although coordination and day-to-day control might be a little more difficult, organizations more than make up for the difficulty in quality, flexibility and cost. The result is that specialists are cropping up in practically every major business activity, from product design to delivery, and it's now possible to pull together a virtual organization that employs only "best-of-breed," cost-effective contributors at each points (Melnicoff, 1999).

Banks, consumer-packaged-goods companies, insurance providers, educational institutions, manufacturing firms, and health care providers are cutting the value chain and enhancing business relationship by utilizing the Internet and its offshoots, intranets and extranets (Internet Commerce, 1999).

Clearly, it is important for organization to focus on the part of the value chain most valued by customers and team up with the best for the rest. Specialized niche players or smarter, faster competitors will attack any weak parts of your value proposition and marketing position. If you're not the absolute best at performing a function that can be bought elsewhere, don't do it. (Melnicoff, 1999)

In the business-to-business arena, e-commerce strategies allow businesses to leverage electronic alliances to speed up the delivery of products and services to market. Companies set up electronic linkages to work more closely with their suppliers and save millions of dollars in inventory and distribution costs.

Internet-based procurement solutions leverage the Internet as a business and technology enabler, using workflow-driven process automation and supply-chain collaboration to streamline purchasing and reconcile payments. The procurement personnel can be deployed strategically for analysis and sourcing. By automating the generally paper-based procurement of maintenance supplies, office supplies, equipment, services, and the like, companies can realize substantial cost savings (Internet Commerce, 1999)

Customer Relationship Management

In order to be successful in the market–driven economy, customer satisfaction is the top priority for all organization. With greater reach of information through proliferation of Internet, global marketplace offers customers with unlimited choices of products and services. Customers demand instant access to product information, e.g. features and pricing, ease in ordering products and choices of payment methods.

Customers and suppliers who have embarked on e-commerce initiatives are beginning to demand their business partners to jump on their bandwagon to further streamline their business processes. In certain case, it has become mandatory for company to adopt and draw up a plan to embrace e-commerce in order to continue their business dealings or partnership.

Cisco has become a world leader in Internet commerce by winning customers with streamlined, self-service business processes. Unassisted Web sales account for roughly 73 percent of Cisco's $8.3 billion per year in orders. Customers and business partners also have direct access to technical support and order status information, saving Cisco $550 million annually while improving customer satisfaction (Internet Commerce, 1999).

Customer motivations can be examined in categories of benefits, rewards and relationships. Customer values can be examined in terms of an individual's value assessment of risk and benefit, particularly as those values relate to the use of electronic commerce technologies.

Bitner (1995) describes an encounter between a business and a customer and the associated relationship building around the concept of "promises". Bitner poses three components of promises: making promises; enabling promises; and keeping promises. The three components of promises translate roughly to the marketing, advertising, and sales functions; the electronic servicescape for direct customer interaction; and the fulfillment process and supporting infrastructure. Electronic commerce offers the opportunity for an entire transaction process - advertising, purchasing decision, and order fulfillment - to occur within one customer interaction at the electronic servicescape.

Stone (1994) describes "relationship marketing" not only as a benefit to a direct marketing industry company, but as a necessary condition to profitability. Stone recognizes that the first sale to a direct marketing customer is not profitable when considering all of the costs associated with obtaining that customer. Given that investment in obtaining a new customer, it is logical and essential to develop and maintain a long-term mutually beneficial relationship with that customer that results in repeat sales. This is the business rationale behind the practice of database marketing.

This recognition of relationships as a necessary foundation for profitability in an industry that has direct contact with individual customers is one of the reasons the catalog industry is considered a precursor of electronic commerce is because they have been doing this over the last two decades.

Electronic collaboration is the most important part of the business-to-business electronic relationships - two companies leveraging each other's information systems to enhance the overall customer experience. Thanks to the tight electronic links enabled by the Internet, global express-delivery company United Parcel Service (UPS) provides most of the shipping for the world's largest PC manufacturers. UPS is adding value to the business transactions to each of the major customers (Internet Commerce, 1999).

Once customers configure their orders for computers and peripherals, UPS and its partners coordinate the shipping activities for multiple locations, drastically reducing the manufacturers' inventory carrying costs and ensuring that all pertinent packages arrive at the customer's location on the same day. Customers can track their shipments through the UPS delivery network, using a single order number. Far beyond providing mere transportation services, UPS is a trusted partner, enabling these companies to offer more efficient routing, and fulfillment services – all of which lead to greater customer satisfaction (Internet Commerce, 1999).

The focus on customer relationships and the evolutionary approach described by these organizations is in contrast to much of the hype surrounding the Internet and World Wide Web which suggests some kind of revolution in the making through radical new approaches to commerce (Wanninger, 1996, 1997).

RESEARCH METHODOLOGY

E-commerce (electronic commerce) solutions bring the open standards and universal access of the Internet to the core business processes of buying and selling goods and services. This is a great promise for a lot of companies to jump start into E-commerce, but generally a lot of companies are relatively cautious in adopting E-commerce initiatives. Some pioneers, for example Amazon.com, who has been operating online retailing business for sometime are still struggling to make the company a profitable one, but others like example Cisco is doing wonders with their E-commerce efforts.

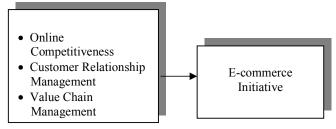
E-commerce is being adopted by many organizations in their business model, which emphasizes speed, efficiency and customer relationship. Studies on critical success factors for numerous organizations shows online competitiveness, customer relationship management, and value chain management are becoming driving factors in today's competitive marketplace. Therefore, online competitiveness, customer relationship management, and value chain management would influence in e-commerce initiative. Organization's internal factor, such as the organizational setting is another factor that may impact the e-commerce implementation. Organizations need to have an appropriate culture and setting to adopt e-commerce successfully. Figure 2 provides a graphical representation of the conceptual theoretical framework.


Figure 2: Conceptual Model of Driving Forces in Commerce Initiative

HYPOTHESIS

Malaysia attracts large numbers of foreign investments in the manufacturing sector, primarily in the electrical and electronics industry, which is the top export earner. The value of electrical and electronic products grew by 22% in 1999 to RM 185.3 billion, and accounted for 57.7% of all exports from Malaysia (The Star, 5-Feb-2000). In the globalization age, Malaysian companies need to be well equipped with enabling technologies to be competitive in the open marketplace.

The small and medium industries (SMI's), which are providing products and services to the multi nation corporations (MNC's), will continue to the centre of growth for Malaysian based companies. Due to better IT infrastructure and exposure in their homeland, MNC's are generally thought to be the forerunner on e-commerce initiative. In the quest to streamline their business processes, MNC's will be slowly imposing e-commerce requirements on SMI's for continual business transactions.

Hypothesis 1 is intended to study the differences in e-commerce readiness level between companies of various equity holding, this is to test if Malaysian companies are lagging in e-commerce readiness.

Hypothesis 1: Equity holding structure is influencing decision of electronic commerce initiative.

Online competitiveness, value chain and customer relationship management are being pursued by many organizations to be their core values in their business processes. Most other literatures also put forward business models, which include these elements. Hypothesis 2 is intended to test impact of these variables in affecting decisions on e-commerce adoption.

Hypothesis 2: Online competitiveness, customer relationship management and value chain management are influencing decision of electronic commerce initiative.

DATA COLLECTION AND MEASUREMENT

The target population for this study consists of manufacturing firms located in Free Industrial Zone in the state of Penang and Kedah. From the Penang Development Guide, it was estimated that the manufacturing population would be about 300 companies. Sources from Perbadanan Kemajuan Negeri Kedah (PKNK) indicated there were about 150 companies operating in Industrial Zone in Sungai Petani and Kulim.

This study required that the sample to have Internet connectivity and other IT infrastructure setup, with appropriate understanding and exposure to Internet transaction functionalities and capabilities. Given the situation, the probabilistic method of sampling would not have achieved the level of accuracy and confidence desired in this study. As such, the purposive judgmental sampling method was used in the sampling design.

Data collection was primarily done by personal delivery and mail. A number of sampled companies selected were contacted to identify individuals to answer the questionnaire, others are addressed to the IS manager of the company. The respondents for this study were the decision makers or IT personnel influencing decision making in investment in computerization projects. A self-addressed, stamped envelope was included to facilitate the return of the completed questionnaire. Some of the questionnaires were distributed by IT vendors, who knew their clients well and were in regular contact with them, and the return rate were expected to be higher.

The questionnaire was sub-divided into several sections. Section A consisted of 7 general questions, where respondents were requested to provide some general information pertaining to individual and organization profile. Section B has 4 questions that are intended to reveal more information about respondents' IT infrastructure setup. Section C has 17 questions correspond to Online Competitiveness, Customer Relationship Management, Value Chain Management. Each item in section C was measured on a 6-point Likert scale anchored by 1 (Strongly Disagree) and 6 (Strongly Agree), with the response of 6 indicating the element strongly influencing e-commerce initiative.

In order to ensure the reliability of the measures, the multiple statements on Online Competitiveness, Customer Relationship Management and Value Chain Management were assessed with Cronbach's Alpha reliability test. The alpha value ranges from 0.73 to 0.88. The values of Cronbach Alpha indicates high reliability of measurement for all the independent variables. Table 1 shows the alpha value for all variable grouping.

Table 1: Cronbach's Alpha Value for Variable Grouping

Variable	No. of Items	Cronbach's Alpha
Online Competitiveness	7	0.8766
Customer Relationship Management	5	0.8116
Value Chain Management	5	0.7313

RESULTS

A total of 220 questionnaires were distributed through mail, MBA course-mates and IT vendors, only 115 were collected from respondents in this survey. Of the 115 received, only 85 are usable for the purpose of this study. The response rate was approximately 52%, while the overall response rate was about 39%. Table 2 shows the profile of the sample.

Table 2: Respondent/Organization Profile

Profile	Description	Number	%
Designation	Managing Director	9	10.6
	Director	7	8.2
	Department Manager	24	28.2
	Section Manager	45	53.0
No. of Employees	Less than 300	32	37.6
	Between 301 to 2000	27	31.8
	More than 2000	26	30.6
Equity Structure	USA	41	48.2
	Japan, Taiwan, Korean	9	10.6
	Europe	7	8.2
	Malaysia	28	33.0
IT Awareness	Low	7	8.2
	Medium	39	45.9
	High	39	45.9

Of the 85 respondents, nine were Managing Directors, seven were Directors, twenty four were Department Managers, while forty-five Section Managers make up 53% of the respondents. As for the organization profile, 32 companies have less than 300 employees, while 27 companies have between 301-2000 employees and 26 companies have more than 2000 employees. On the equity holdings of the responding organizations, the majority of companies, 67% or 57 companies were foreign owned. Of the 57 foreign owned companies, 41 companies are USA-based, while East Asia (Japan, Taiwan and Korea) and Europe have 9 and 7 respectively.

IT awareness for the responding companies were relatively high, with 39 companies having high awareness level, 39 companies with medium awareness, and only 7 companies having low awareness.

E-Commerce Readiness Profile

There were five levels of e-commerce readiness being measured in this study, 47.1% of the responding companies were already using e-commerce to perform business transactions, 10.6% has plans to start e-commerce in the next six months, 14.1% planned to implement e-commerce between six to twelve months, 20.0% may adopt e-commerce in more than twelve months, while 8.2% or seven companies has no plan in place for e-commerce.

Table 3: E-commerce Readiness Profile

Profile	Description	Number	%
E-commerce readiness			
5	Already in place	40	47.1
4	In the next 6 months	9	10.6
3	Btw 6 to 12 months	12	14.1
2	More than 12 months	17	20.0
1	No plan as yet	7	8.2

The descriptive analysis below shows that the mean for all the three variables Online Competitiveness, Customer Realtionship and Value Chain Management is high. This further strenghtens our postulation that these three variables strongly influences the e-commerce readiness.

Table 4: Descriptive Statistics of the Composite Variable

Variable	Mean	Std Deviation
Online Competitiveness	4.69	0.78
Customer Relationship Management	4.72	0.74
Value Chain Management	4.37	0.73

Influence Of Equity Holding Structure On Electronic Commerce Initiative

Results of the test of differences (Kruskal-Wallis One-Way ANOVA) is shown in Table 5. The test is significant which indicates that equity holding is influencing decisions on e-commerce initiatives. From the mean ranking we can see that the USA based companies are much much e-commerce ready compared the the other three regions.

Table 5: Mean Rank Result by Equity Structure

	N	Mean Rank
E-commerce Readiness		
USA	41	51.28
East Asia	9	36.33
Europe	7	37.64
Malaysia	28	34.43
Total	85	
Chi Square		11.072

Asymp. Sig.		0.011

Influence Of Online Competitiveness, Customer Relationship Management And Value Chain Management On Electronic Commerce Initiative

For multiple discriminant analysis, the e-commerce readiness levels were separated into three groups, namely group 1 (No plan as yet), group 2 (In the next 6 months, Btw 6 to 12 months and More than 12 months), and group 3 (Already in place). Group 1 has 7 companies, group 2 has 38 companies, and group 3 has 40 companies.

Table 6: Hit Ratio for Cases Selected in the Analysis

Actual Group	Cat.	N. of Cases	Predicted Group Membership		
			1	2	3
No Plan Yet	1	6	4	2	0
			66.7	33.3	0.0
Planning	2	22	3	15	4
			13.6	68.2	18.2
Implemented	3	33	0	6	27
			0.0	18.2	81.8

Note: Percentage of "grouped" cases correctly classified: 75.41%

Table 7: Hit Ratio for Cases in the Holdout Sample

Actual Group	Cat.	N. of Cases	Predicted Group Membership		
			1	2	3
No Plan Yet	1	1	0	1	0
			0.0	100.0	0.0
Planning	2	16	0	12	4
			0.0	75.0	25.0
Implemented	3	7	0	1	6
			0.0	14.3	85.7

Note: Percentage of "grouped" cases correctly classified: 75.00%

Table 8: Comparison of Goodness of Measure

Measure	Value	Hit Ratio for Holdout Sample
Maximum Chance	66.6%	75.00%
Proportional Chance	53.12%	75.00%
Press Q		
Table Value		6.635
Calculated Value		18.75**

Note: ** significant at $\alpha = 0.01$

Table 9: Summary of Interpretive Measures for Discriminant Analysis

Indep.	Discriminant Function Loading		Univariate	Potency
Variable	Function 1	Function 2	F Ratio	Index
Online	0.847	-0.108	29.092	0.702
Value	0.787	0.999	17.635	0.628
Customer	0.651	-0.710	25.225	0.426

For the discriminant analysis the sample was divided into two portions, with the first group called the cases selected (used for estimation) and the second group called the holdout sample (used for predictive accuracy). This is done to test the internal validity of the model and assessment of its predictive accuracy.

As can be seen in Table 6 and 7 the predictive accuracy of the model is 75.41% and 75% respectively. What can be concluded here is that by using the three variables of online competitiveness, customer relationship management and value chain management we can classify the respondents according to their e-commerce readiness.

To test further whether the model is good three tests were conducted as depicted in Table 8, the hit ratio exceeds both the maximum likelihood and proportional chance criterias. Also it is signicant at 0.01 using the Press Q statistics.

Table 9 shows the interpretive measures where the discriminat function loadings, univariate F ratio and also the potecny index is presented. From the potecy index we can conclude that online competitiveness is ranked the most important followed by value chain management dan customer relationship management in influencing e-commerce initiatives.

DISCUSSION

This study is an exploratory study in which the researcher is interested in identifying the major factors driving the initiative on e-commerce strategy. This study is also intended to establish if Malaysian companies operating in the FIZ Penang and Kedah are lagging in initiative in adopting e-commerce compared to foreign companies.
This study found Online Competitiveness, Customer Relationship Management and Value Chain Management are factors significantly affecting e-commerce initiative for manufacturing companies operating in FIZ in the state of Penang and Kedah. This is consistent with opinions of most IT experts in the e-commerce, and may serve as a guideline for other companies in evaluating e-commerce project implementation.

Most companies operating in FIZ Penang and Kedah have been in business for a number of years and they are relatively up to date in IT deployments, the Internet connectivity has provided them an effective medium to enhance their strengths in online competitiveness, customer relationship management and value chain management. These strengths will enable them to operate efficiently and improve their ability to respond to competitive pressures on costs, speed and quality.

Due to geographical reasons and lagging in advanced IT infrastructures and technologies, Malaysia is generally seen as slow in adopting new and enabling technologies. Malaysian companies are expected to fall behind foreign companies in e-commerce initiative in this study. This study found American companies are leading Malaysian companies in e-commerce initiative. However, this study found Malaysian companies on par with European and East Asian companies in e-commerce initiative. The purposive judgmental sampling method employed in this study may also have caused the good rating on Malaysian companies in e-commerce initiative.

Records from IT vendors have shown more than 50% of responding Malaysian companies are well equipped with substantial IT infrastructure setup, e.g. EDI, ERP applications and groupware applications.

Many multinational corporations have been operating in FIZ in Penang for more than 25 years, and most of them frequently imposing requirements for good IT infrastructure setup on their business partners. Over time, these Malaysian companies supporting the multinational corporations have also upgraded their facilities and technology adoption to be on par with their major customers for continue-businesses. At least three responding Malaysian companies are KLSE listed companies, which are well managed, are known to have IT infrastructure and applications on par with other multinational corporations.

IMPLICATIONS OF FINDINGS

The findings suggest several general implications. This study enlightens us about Malaysian companies' readiness into e-commerce. Malaysian companies are only lagging behind American companies, but on par with European and East Asian companies in electronic commerce initiative. This is in contrary to general perception that Malaysian companies are lagging in IT implementation. Inline with the 7th Malaysian Plan (The Star, May 7 1996) to help local companies to be IT ready as we are moving towards more open and challenging marketplace in the globalization age, a lot of Malaysian companies may have heed the government's advise and take up the challenge.

Malaysian manufacturing companies, particularly in the small and medium industries operating in Free Industrial Zone in Penang and Kedah, are mostly relying on MNC's for business. They enjoy comparative advantages in lower labor cost, availability of skilled workforce, and government protection from foreign competition. Foreign direct investment in Malaysia has slowed down recently, especially after the Asian financial crisis. Malaysian manufacturing companies need to look into expanding their current market for continued business and future growth. The world is moving into the trade liberalization era, transitioning from GATT to WTO, barrier and control on international trade will be dismantled stage by stage. As we are moving into a bigger and more open economy, American companies with its global presence and size, coupled with its efficiency achieved through effective management, and new and enabling information technology will continue to dominate the world market. Malaysian companies can emulate the American companies in adopting e-commerce strategy to compete more effectively in the globalization age.

In today's 'Networked Economy', where individuals and companies worldwide are being electronically linked, e-commerce will be a norm in time to come. Companies should continue to evaluate effective strategy to maintain international competitiveness. Online competitiveness, customer relationship management and value chain management are important strengths for Malaysian companies to acquire or enhance further to compete effectively in the open global marketplace.

E-commerce is an enabling technology for smaller Malaysian companies to engage in business with their customers worldwide; with informative web site hosted by Internet service providers, they can attain online competitiveness with greater market reaches and well-profiled interactive web site resources enhance customer relationship. Logistics and payment gateways can be managed by established courier service and bank with no start-up cost. This enables smaller companies to compete effectively as other bigger companies which have establishment on sales, marketing, finances and distribution functions in their organizations. Smaller Malaysian companies can concentrate their limited resources into their core competency to develop competitive products and services. Malaysian companies that have not planned or embarked on e-commerce can use this study as a guideline in evaluating their strengths in online competitiveness, customer relationship management and value chain management.

ABSTRACT

In an effort to advance the development and adoption of e-commerce by SMEs in Sarawak, this study is an attempt to provide an overall view on e-commerce adoption, e-commerce application, possibilities and avenues in relation to local SMEs. It identifies the barriers and obstacles which inhibit the adoption of e-commerce. It also highlights the critical success factors regarding the development of e-commerce. It has been observed that the political, economics, social and technological issues affected e-commerce adoption. Conclusive evidence from the survey established the fact that using e-commerce to open up wider market share can be achieved by providing online services and advertisement, the establishment and promotion of internet culture, upgrading securities, mapping global market accessibility, and the building of information centres to address gaps in promoting the use of e-commerce. The provision of the supporting services and the related measures taken will give SMEs a better understanding of the benefits of using e-commerce resulting invariably in more participation and ultimately adoption. Finally, this study also provides suggestions and recommendations to individual SMEs and governmental bodies to facilitate them to carry out Research and Development studies or programmes in due course.

INTRODUCTION

The rapid growth of the internet as a consumer technology has led to the accelerated use of electronic commerce (e-commerce) nationally as well as globally. E-commerce through the internet is a new way of advertising, buying, selling, and in some cases, delivering goods and services. There has been much hype about the potential of the internet to transform supply chains and business processes. Despite the setbacks following the deflation of the 'dot.com bubble' in the United States and elsewhere, the internet is beginning a new phase of adoption and utilization (Industry of Tourism and Resources, 2002). E-commerce not only affected business and individual consumers, but it also reshaped market places, trading relationships and even international trading boundaries.

The important of small and medium-size enterprise (SME) in e-commerce can be reviewed from past studies. Burgess (1998) concludes that for SMEs they must be involved in e-commerce one way or another if they are to survive. Survey done by Foley, Sutton and Jayawardhema (1999) has provided some interesting statistics that continues to add value to the argument that all businesses should be involved in e-commerce. However, they also show some confusing and conflicting results generated from e-commerce surveys and predictions. Using these figures it appears that small, medium or large businesses must be doing e-commerce to remain competitive.

In view of the potentials and concerns on e-commerce, as mention in Eighth Malaysia Plan, a National Electronic Commerce Committee was set up to formulate a framework aimed at promoting and coordinating the development of e-commerce (Economic Planning Unit [EPU], 2001a). Looking at the SMEs capabilities, the Third Outline Perspective Plan state that Malaysian SMEs serve as strong foundation to anchor the nation's industrial sector, encourage working towards establishing and strengthening their own niches in the market and emerging as market leaders in their own right (EPU, 2001b).

Former prime minister and minister of finance Malaysia, Dr. Mahathir Mohamad (2001), in his 2002 National Budget state that "In order to compete in the international market, small and medium companies must participate in the Global Supply Chain Management Network for online and real-time procurement, production and logistics management". In line with the national direction, the Sarawak government continue to provide the information and communication technologies (ICT) infrastructure and facilities that are required to promote ICT and to narrow the digital divide among the urban and the rural populace, the private sector's role is also critical in the development of e-commerce in the state (Taib, 2002).

Definition Of SME

Every country has a different definition of what SME is, while some counties do not have a clear definition of SME. So the definition of SME for this study is based on Malaysian government agencies, Small and Medium Industries Development Corporation (SMIDEC, http://www.smidec.gov.my) and SMI Association of Malaysia (http://www.smisme.com). Both of them define as manufacturing companies or companies providing manufacturing related services with annual sales turnover not exceeding RM25 million and full-time employees not more than 150 (Asian-Pacific Economic Cooperation [APEC], 1998).

E-Commerce Perspective

Similarly with the definition of SME, it is difficult to find a consistent definition for e-commerce. Several definitions of e-commerce have been developed and used in different contexts and for varying purposes. The following are a few selected definitions for e-commerce in differences perspectives. APEC (1998) mention that "there are a number of levels of engagement in e-commerce that require different levels of infrastructure and involve different costs, e-commerce needs to be recognized as covering a broad range of activity". IBM (http://www.ibm.com) describes e-commerce terminology as "the subset of e-business that involves the exchange of money for goods or services purchased over an electronic medium such as the Internet". Iowa State University (http://www.iastate.edu) state that "all activities related to interaction between two trading partners except production and delivery of physical goods and services". Kalakota and Whinston (1997) recognize that there are various definitions of e-commerce depending on different perspectives, which includes communications, business process, service, and online electronic processing. Kalakota and Whinston (1997) do provide a general definition as "e-commerce emphasizes the generation and exploitation on new business opportunities and, to use a popular phrase: 'generate business value' or 'do more with less'". Organisation for Economic Co-operation and Development (OECD, 1999) has adopted a policy driven definition as "business occurring over open, non-proprietary networks such as the Internet". TechRepublic (2000) specifies that "the use of communication technologies to transmit business information and transact business, taking an order over the telephone is a simple form of e-commerce. Internet commerce is also e-commerce but is only one of several advanced forms of e-commerce that use technology, integrated applications, and business processes to link enterprises". Turban, Lee, King and Chung (2000) define e-commerce as "the process of buying and selling or exchanging of products, services and information via computer networks including the internet". Conclude all the above definition from various perspectives, the definition of e-commerce should embody the notion of ICT adding value to commerce and some implied concept that includes the value chain. That is, ICT enhances an organizations capability in the trading of goods and services between two parties who are part of their value system. Thus the definition for e-commerce that is applied in this study defines as the use of computers and electronic networks to conduct business over the Internet or other electronic network.

PROBLEM STATEMENT

SMEs are significant players in Sarawak business, which constitutes more than 90 per cent (Department of Statistics, 2003) of all business establishments. SMEs that can demonstrate their capabilities to use e-commerce will have a competitive advantage in e-commerce market. Are SMEs aware of progress in the area, and work towards identifying potential barriers and problems, solving any problems, and exploring opportunities and benefits for SMEs in Sarawak? Are the local SMEs going to be bystanders or to participate in the mainstream of e-commerce development? For those SMEs which are ICT illiterate, if they are going to develop a more sustainable and durable organization, they must move away from the traditional subsistence activities, change their mindset, attitudes, thinking and approaches. They must be ready to change either gradually or through a quantum leap.

According to Taylor Nelson Sofres Interactive, e-commerce is stumbles in Malaysia (Nua, July 13, 2001). It is to understand the level of adoption business focus in the development of internet with ICT and the expansion of e-commerce, it is imperative for SMEs to look for ways to ensure a more successful venture into e-commerce, to find out the possible strategies that SMEs should formulate and implement in order to establish more appropriate business model which can sustain in this changing world.

Beside that, the state government of Sarawak can have a better understanding in focusing on policy setting in stimulate the e-commerce development by assess the success elements on how the community uses e-commerce with an emphasis on the potential opportunities and perceived benefit of e-commerce.

OBJECTIVES

The purpose of this study is to achieve the following objectives concerns the development of e-commerce for SMEs in Sarawak.

- To discover the impact of e-commerce on the SMEs through the analysis of their business management and information technologies.
- To know how SMEs perceive security and legal issues, and their opinion as to their importance to the uptake of e-commerce.
- To assess how SMEs perceive economies' interventions to promote and support the adoption of e-commerce.
- To analyze and work out a strategy to help SMEs face the impact of e-commerce; with an emphasis on the potential opportunities and perceived benefits of e-commerce by SMEs.
- To evaluate the barrier and propose concrete ways in which SMEs can eliminate barriers that may deter them from becoming part of the digital economy.

The study results will provide recommendation options for Sarawak's state government to promote e-commerce develop future work plans and serve as guide for policy setting and analysis functions and technology pilot project selection. Beside that, this study results should also help the SMEs who intend to go for e-commerce as a reference, to enjoy the opportunities offered and aware of the threats in e-commerce development. But for e-commerce service providers, this study will provide a clear understanding for them to decide what direction to focus on in order to assist the SMEs to minimize investment and gain maximize return.

THEORETICAL FRAMEWORK

This study was to undertake a qualitative assessment of the adoption, uptake and use of e-commerce by SMEs. It investigated the opportunities, benefits and the real and perceived barriers to the adoption and use of e-commerce among SMEs in the region. In particular, this study sought the opinions of early adopters and users of e-commerce in the SME community. This approach was then used to identify measures, in terms of policies, programs or initiatives, which might be taken by Sarawak government to address the barriers identified by early adopters and thus enable the next wave of SMEs to adopt e-commerce without facing the same barriers.

STATUS OF ICT AND E-COMMERCE READINESS

Despite the setbacks suffered by e-businesses in 2000, the government was a major promoter of Internet growth, continuing with plans to create a knowledge-based economy and increase Internet penetration to 25% by 2005. (Economist Intelligence Unit [EIU], 2001) Support measures introduced in the past year include a new M$500m venture-capital fund, tax incentives for venture capital for technology firms and other high-risk investments, ongoing implementation of the technology-oriented Multimedia Super Corridor (MSC), and a whole slate of new laws on protecting intellectual property. The government also created several new agencies in 1998 to regulate and advance Internet growth (EIU, 2001, July 9).

As shown in table 1, Malaysia is ranking at 32 of 60 countries being rated globally by EIU on e-readiness. It is position at the second highest as a follower among the ASEAN 5, where as Singapore is maintain as a leader in e-readiness and top position in ASEAN 5 countries. The potential of e-commerce development in Malaysia are relatively high. Table 2 shows Malaysia recorded 1.7 million of dollars in 2002 and expected to growth to 18.4 billion of dollars in the next 4 years, with the higher compound annual growth rate of 81.4 per cent.

Table 1: E-Readiness Rankings, 2003

Country	2000	2001	2002	2003	E-readiness (%)	E-business Group
Indonesia	38	54	52	53	33.1	laggard
Malaysia	32	33	32	33	55.5	follower
Philippines	46	39	49	47	39.3	follower
Singapore	8	7	11	12	81.8	leader
Thailand	28	46	46	42	42.2	follower

Note: Decimals have been rounded.
%: Per cent weight in overall score.
E-business Group: leaders: These countries already have most of the elements of "e-readiness" in place, though there are still some concerns about regulatory safeguards.; followers: These countries--the largest group in the rankings-- have begun to create an environment conducive to e-business, but have a great deal of work still to do.; laggards: These countries risk being left behind, and face major obstacles to e-business growth, primarily in the area of connectivity (EIU ebusiness forum, 8/5/2001).

One of the major government initiatives in stimulates supply and demand on ICT market was setting up MSC, which is the most ambitious project to create Malaysian "Silicon Valley". Figure 1 show the statistics of all the sectors approved by MSC as at 13th January, 2004. Internet based business, e-commerce service or solution provider is one of the top 3 popular sectors in MSC flagship project in reaching catalyst for ICT development through the country.

Note: a - Software Development - Business Applications
      b - Software Development - Eng. & Specialised Apps.
      c - Internet based Business - E-Commerce service / solution providers
      d - Content Development
      e - Hardware / Electronics Design
      f - Internet based Business - Application Service Provider
      g - Education / Training
      h - Systems Integration

Figure 1: Approved MSC Companies as of 13th January 2004

Take closer look at the e-readiness by EIU resent ranking on Malaysia, figure 2 illustrated all the six categories that influence the ranking system. The business environment seems to gain competitive advantage in all factors. Connectivity and technology infrastructure is the enabling factor to move e-commerce; it is not well covered through the country, indirectly, it slow down the development, on promoting e-commerce locally, there is another additional common infrastructure need to take into consideration.

Evaluation on how prepared the country is to capture the benefits of technology to promote economic growth and productivity is a comprehensive assessment done by World Economic Forum, Out of 82 countries ranked in the Global Information Technology Report 2002-2003 (Dutta, Lanvin & Paua 2003). Currently Malaysia is also ranked at 32 in Networked Readiness Index. Whereas it's neighboring Singapore is ranked at no 3, it can be a good example to follow.

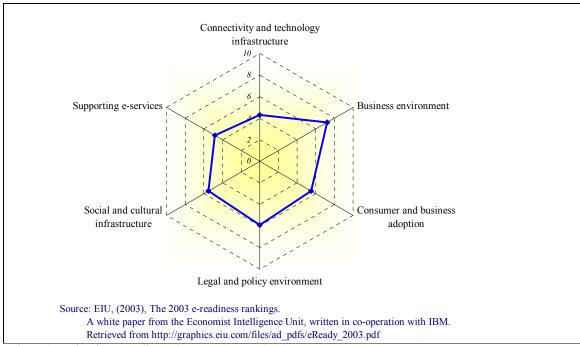

Figure 2: Malaysia E-Readiness Category Scores, 2003

Another encouraging element is on the registration of internet domain name, from table 3, the new Malaysian commercial domain name registration is maintain at higher growth, it is more than a total of 40,000 commercial domain name registered since 1995. It really shows the growth of this new emerging market, the availability of local businesses in internet presence, despite of bursting of the dot-com bubble, Asian economic crisis and global economic slowdown.

Focusing on SMEs in Sarawak, figure 3 indicate industry sectors like food processing, garments, machinery and equipment, structural and fabricated metal products cover 70 per cent of SMEs establishment. Figure 4 shows the basic ICT infrastructure in Sarawak. There is a huge potential to introduce internet and personal computer to the household because the census 2000 by Department of Statistics shows that there is a total of less than 10 per cent of household have internet and personal computer.

Table 3: Total Number Of .My Domain Name Registrations

Year	*.com.my	*.net.my	*.org.my	*.gov.my	*.edu.my	*.mil.my	Total
1995	100	3	4	31	13	-	151
1996	537	32	30	73	42	-	714
1997	1,306	61	37	57	30	-	1,491
1998	2,061	86	42	62	61	-	2,312
1999	4,738	222	144	64	63	-	5,231
2000	10,048	378	192	51	74	-	10,743
2001	7,372	348	204	83	111	-	8,118
2002	7,514	334	216	81	126	1	8,272
2003	8,030	408	289	99	154	3	8,983
1995-2003	**41,706**	**1,872**	**1,158**	**601**	**674**	**4**	**46,015**

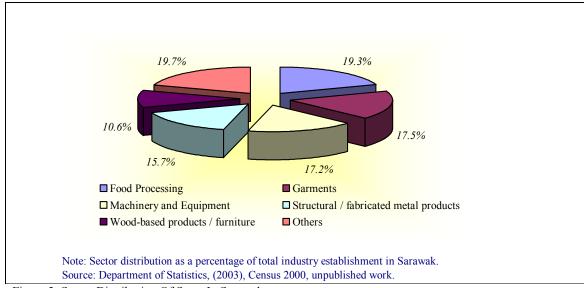
Note: Sector distribution as a percentage of total industry establishment in Sarawak.
Source: Department of Statistics, (2003), Census 2000, unpublished work.


Figure 3: Sector Distribution Of Smes In Sarawak

Besides that, with the globalization and liberalization, government effort and support is the driver of e-commerce adoption. Sarawakian must face the challenge and compete with the outside world.

E-COMMERCE ADOPTION AND DEVELOPMENT

According to Chambers of Commerce of Ireland (2002) on chamber SME e-business survey 2002; there is about 84 per cent of internet penetration rate within the SMEs market and 50 per cent of SMEs have their own websites. From United Kingdom's national statistics (2002) results for 2001 e-commerce survey of UK businesses indicate that 46 per cent of the smallest sized businesses were online, compared with 98 per cent of businesses with 1,000 or more in employment. Indirectly, it is means that the larger the business the more likely it is to be online.

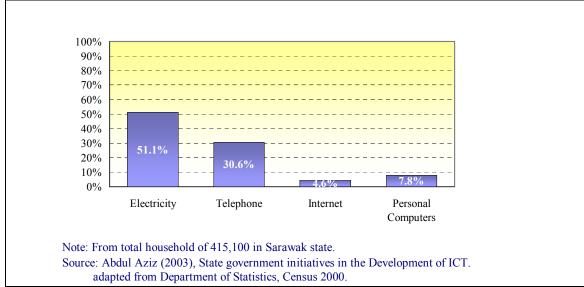
Note: From total household of 415,100 in Sarawak state.
Source: Abdul Aziz (2003), State government initiatives in the Development of ICT.
adapted from Department of Statistics, Census 2000.


Figure 4: Basic ICT Infrastructure in Sarawak

With realizing the important of online, internet and e-commerce, the Malaysian government initiates two sub-committees chaired by the Ministries of International Trade and Industry (trade and finance) and Ministry of Energy, Communications and Multimedia (infrastructure) obtained the endorsement of the Cabinet to use the National Electronic Commerce Strategic Directions as the strategic document for related ministries and

government agencies. (Multimedia Development Corporation [MDC], http://www.msc.com.mt/mdc) The report document seeks to identify and describe the most prospective areas for national initiatives to begin the task of securing Malaysia's e-commerce future. (Ng, 2003; Mazlan, 2003) From the surveys conducted for 800 SMEs throughout country, about 90 per cent had computers, just over half had internet access and less than 20 per cent had a web sites. Less than 5 per cent of Malaysian companies had implemented internet payment system in 1999 (MSC Technology Centre, 1999). This shows the status of e-commerce progress in Malaysia, and the government are played their role in facilitating the use of e-commerce for SMEs and in increasing their ability to reap the benefits (e.g. via awareness building and training programme). The governments also in partnership with the private sector to establish a more comprehensive and consistent policy approach to SMEs and e-commerce, and apply evaluation mechanisms to assess what works and does not work (UNCTAD, 2001).

To re-intermediate the economic competitiveness in the manufacturing sector with emphasis on the electronic and electrical clusters, Technology, Industry and Government working together for E-economic Revolution (TIGeR) project provides an integrated platform for collaboration between manufacturers with their global and local buyers and suppliers, the strategy is to encourage SMEs to adopt and implement e-business applications for on-line real-time participation with an e-community of multi-tier suppliers, manufacturers, buyers and governmental bodies (Tengku, 2002; Latifah, 2002).

BENEFITS OF E-COMMERCE

The adoption of electronic commerce by SMEs depends largely on their perception of the opportunities and benefits afforded by electronic commerce and the relevance of these opportunities to their business. As shown in table 4, most SMEs participating in the survey by APEC (1999) are optimistic about the potential benefits that e-commerce can bring to their business.

Benefit to Consumers

Electronic commerce enables firms to be more responsive to customer needs and more efficient in interacting with and servicing business and consumer needs. SMEs value the fact that e-commerce enables them to offer 24-hour per day information to customers through their Internet web site and respond more quickly to customer inquiries and requests for information by email. E-commerce allows SMEs to be more targeted in their customer communications and realize more cost reductions in their advertising and product promotion. They value the ability to standardize customer information digitally and update it efficiently and at lower cost. SMEs believe that e-commerce will enable them to gather and compile better market intelligence on their customers, suppliers and competitors through Internet research and better develop and update customer databases, including online databases. By providing a higher quality of service and better information exchange with customers, SMEs believe that e-commerce will offer important benefits in improving longer-term customer loyalty and retention.

Table 4: Potential Benefits Of E-Commerce Use By Smes

Rank	Top 10 Benefits
1	Improve customer service
2	Enhance company image
3	Customer information exchange
4	Improve competitive position
5	Increase customer loyalty
6	Access international markets
7	Increase revenue
8	Reduce costs of information
9	Supplier information exchange
10	Attract new investment

Source: APEC. (1999). SME Electronic Commerce study,
Exhibit 2.1

Improving the company image and competitive position is a very important perceived benefit of electronic commerce. Many participating SMEs believe that e-commerce can enable firms to develop a presence and compete in markets that were previously untapped by SMEs. Traditional barriers such as distance,

communications costs and access to international markets that prevented SMEs from competing with larger firms are not as significant. Electronic commerce can remove some of these barriers and SMEs recognize this as an important benefit of developing their e-commerce capabilities.

Benefit to Organizations

SMEs with higher levels of e-commerce capability identified using e-commerce to increase revenues and reduce procurement and information costs as a more important benefit than firms with lower capability. This suggests that SMEs with higher e-commerce capability levels may be more advanced in integrating e-commerce into their overall business models, and thus have higher expectations on revenue and cost benefits derived through e-commerce than do SMEs with lower levels of capability. Firms of this type typically use e-commerce to reduce product inventory, decrease warehousing costs or shorten sales and distribution cycles.

Benefit to Society

Participating SMEs with higher levels of e-commerce capabilities were more likely to identify using e-commerce to reach international markets as an important benefit. This suggests that for many SMEs, the desire to access international markets may have an important influence on promoting the rapid development of more advanced e-commerce capabilities. Many of these firms further noted that they were using e-commerce strategically to access international markets and had integrated the development of e-commerce capabilities as an important priority of this strategy.

SMEs with higher levels of e-commerce capability were more likely to identify using e-commerce to attract new investment as an important benefit. Firms that identified attracting new investment as more important were often larger enterprises that viewed e-commerce as an opportunity to modify or significantly enhance their business model and value chain thereby enabling the firm to attract new investment more effectively. Some of the SMEs also interested in attracting new investment in information systems (hardware, software) through e-commerce related funding programs.

BARRIERS TO E-COMMERCE

From pass research, Akkeren and Cavaye (1999) has studied the factors affecting e-commerce adoption by SMEs in Australia. They studied that perceived lack of business benefits, mistrust of ICT industry and look lack of time are the main inhibitors to the e-commerce adoption.

CommerceNet's 2000 Barriers to e-commerce survey (Keenan, 2002) laid out the Top 10 Global Barriers for SMEs perspective in expanding into the world of e-commerce. This list is reproduced below:
1. *Lack of qualified personnel:* Cannot attract qualified consultants and staff to implement e-commerce systems for SMEs.
2. *Lack of business models:* There are few proven business models that show how SMEs can use e-commerce to profit or expand their business.
3. *Fraud and risk of loss:* SMEs are more concerned about risk from fraud over the Internet.
4. *Legal issues:* Just like contracts, liability, etc. – there are too many legal issues to make it easy for SMEs to use the Internet to transact business with suppliers and customers.
5. *Not sure of benefit:* Most of the SMEs do not understand how e-commerce can really benefit them to gain competitive advantages.
6. *Customers can't find me:* It is difficult to differentiate between SMEs and large enterprises over the Internet.
7. *Partner e-commerce readiness:* This is a new business, most of the consultant or project manager just started to embark on this new market, and there are too few proven business models for SMEs to justify the expense of a major investment.
8. *Inconsistent tax laws:* E-commerce is doing business globally; tax incentive or laws can be varying from countries to countries.
9. *Proprietary technology:* Different computer platform may have their own proprietary design; it is hardly to develop a system suitable across all platforms. Proprietary technology restrict user from switching one system to another without redevelop the whole system. It is not interoperates and cost effective.
10. *Vertical market:* It is different market segment as compare to the traditional structure.

MacGregor, Bunker and Waugh (1998) have studied the e-commerce in SMEs in Australia and has not only discussed the various approaches used by SMEs in their adoption of ICT and have also discussed the reasons why the speculated benefits of e-commerce adoption could not be achieved and that were due to mismatched mechanism and non understanding of business environment.

OVERVIEW OF THE METHODOLOGY

This study required the opinions of early adopters and users of e-commerce in the SMEs community. This approach was then used to identify the issues affecting e-commerce adoption in terms of political, economic, social and technological in Sarawak. It is also to address the barriers identified by early adopters and thus enable the next wave of SMEs to adopt e-commerce without facing the same barriers.

This study employed qualitative methods, reinforced by quantitative techniques, to elicit the views and perceptions of SMEs with regard to potential opportunities, perceived prospects and challenges to the adoption and use of e-commerce. The study was not intended to make a statistical measurement of e-commerce uptake by SMEs in the state.

Population And Sample

Fraenkel and Wallen (1993) mentions the population is the group of interest to the researcher, or the subjects to whom the researcher would like to generalize the results of the study. One of the easier ways of getting all the SMEs in Sarawak is go through the relevant bodies like SMIDEC, Ministry of Industrial Development Sarawak (MID), Sarawak Manufacturer Association (SMA), Associated Chinese Chamber of Commerce and Industry of Sarawak (ACCCIS) or Sarawak Chamber of Commerce and Industry (SCCI). But, it is happened that the problems of getting information from the above sources are mainly because of SMEs are not all register with them, some of the bodies cover only the bumiputra SMEs, and some might cover all companies in Sarawak or Malaysia. Registrar of companies has the entire manufacturing companies in Sarawak, but they can't identify how many of them are SMEs and how many are not operating currently. Department of Statistics Sarawak is the ideal resource of collecting all SMEs in Sarawak. They did their survey regularly; it is considered as more up-to-date and more reliable. So, this study is based on their data as the population of the study.

There are nearly 2000 SMEs in Sarawak based on the criteria of employees less than 150 or annual turnover less than RM25 million. For this study, in order to have more significant result reflected on SMEs status, SMEs who have more than 20 employees will be elected as the sample of representing the entire SMEs to participate in this survey. Sampling refers to the process of selecting these subjects. So, 289 samples were then selected.

Data Gathering Procedure

Since the survey target is all the SMEs in Sarawak, so it is decided that for those SMEs in other location beside Kuching, which is less than half of the total samples, the survey questionnaire and the prepaid returned envelope were together send by post. Follow up by phone, fax or e-mail to the person in-charge. For the SMEs located in Kuching, it is grouping into areas. Later, the questionnaire was distributed either directly by the researcher, or through associates, friends and contacts. Clarifications on how to complete the questionnaire and list of SMEs in the same area to distribute are given. The respondents were given a time frame of about 1 month to complete and return the questionnaire. The questionnaire were then sorted and checked to ensure that they were properly, correctly and completely filled. Those that were incorrectly or incomplete filled were rejected.

When necessary, interviews were conducted with the respondents to understand their business environment. And also gain a better understanding of the pressures that the organization experiences from their trading partners in doing or not doing e-commerce. Managers, especially in charge of ICT development were interviewed via telephone and electronic mail to obtain further clarification.

ANALYSIS OF SURVEY RESULT

The questionnaires was distributed with the prepaid postage returned envelope to all the manufacturing companies or companies providing manufacturing related services which have employees above 20 but not more than 150. So, there were all 360 copies sent. 2 weeks later, follow up call is conducted to those companies situated in Kuching (which cover more than half of the total SMEs) areas, the undelivered copies are then

sending to the respondents again with their new address obtained via conversation. At the same times, interview and observation may also be used in this study to get a clearer understand, feedback and answers from the respondents.

As a result, total of 61 survey questionnaires (response rate: 16.9%) were collected. In this study, the Cronbach alpha (also referred to as coefficient alpha) is 0.9170. It is a high correlation, which means that the scale of questionnaires is reliable and valid.

Background Of Respondents

The socio-demographic characteristics of the respondents include the SME industries, business volume in term of annual sale turnover, and numbers of employees employed are presented in Table 5. The individual personnel who response to this questionnaire are categories into gender, age group, academic qualification are shown in Table 6; years of experience in business and the position hold in the organization are indicate in Table 7.

Table 5: SMEs Industries, Business Volumes And Employees

Vertical industry	Annual turnover (RM million)	Number of employees			
		0-50	51-100	101-150	Total
Food Processing	0-10	13	6	2	*21*
	10-20	0	2	0	*2*
	Sub-total	**13**	**9**	**2**	**23**
Structural / fabricated metal products	0-10	4	4	0	*9*
	10-20	2	2	0	*4*
	20-25	0	2	0	*2*
	Sub-total	**6**	**9**	**0**	**15**
Wood-based products / furniture	0-10	4	11	0	*15*
	10-20	2	9	2	*13*
	Sub-total	**6**	**19**	**2**	**28**
Others Industry	0-10	23	2	2	*28*
	10-20	2	0	0	*2*
	20-25	0	0	4	*4*
	Sub-total	**26**	**2**	**6**	**34**
Grand total		**51**	**38**	**11**	**100**

Note: Number of per cent (%) of total respondents

Analysis the responded SMEs in Table 5, 51 per cent of the total SMEs, their entire employees is below 50 persons, with approximately 86 per cent of them, their annual turnover is below RM10 million. Only 11 per cent of the total SMEs have above 100 employees.

There are 73 per cent of total SMEs have annual turnover below RM10 million and 6 per cent of total SMEs has existed RM20 million of turnover per annum.

From the industry sectors, wood-based products and furniture have 28 per cent responses, Food processing is 23 per cent, structural and fabricated metal products is 15 per cent, and the remaining 34 per cent come from others industry.

Presented in Table 6 are the individual executives who response to this survey. It consists of 49 per cents of male and 51 per cents of female, this represent an equal proportion of gender. But, from 21 to 35 age level, female respondents is 15 per cent more than male respondents in the same age level, and 8 per cent less than male respondents in the next 36 to 50 age level. Age above 50 respondents is only 8 per cent of the total, this may indicate that they are not really aggressive to participate or not knowing much about the development of e-commerce.

Table 6: Respondents' Qualification By Gender And Age

Gender	Age	Qualification Primary	Secondary	Diploma	Degree	Total
Male	21-35	6	11	4	-	*21*
	36-50	-	4	11	6	*21*
	above 50	-	-	2	4	*6*
	Sub-total	**6**	**15**	**17**	**11**	**49**
Female	21-35	17	15	4	-	*36*
	36-50	-	6	4	2	*13*
	above 50	-	-	-	2	*2*
	Sub-total	**17**	**21**	**9**	**4**	**51**
Grand total		**23**	**36**	**26**	**15**	**100**

Note: Number of per cent (%) of total respondents

Beside that, Table 6 also shows that 59 per cent of total respondents' educational qualifications are primary and secondary. This is a good sign for graduates to join the work force and increase their competitive advantage.

Observed Table 7, chairman, chief executive officer or general manager of the organization have above 10 years experience take up 28 per cent out of 36 per cent of both position total, head of department and other executive position have below 10 years working experience take up 52 per cent of total SMEs, so, more than half of the SMEs' executive has below 10 years in business.

Table 7: Respondents' Position And Working Experience

Position	Experience in business (years) 0-5	6-10	11-20	above 20	Total
Chairman, CEO	-	-	2	2	*4*
General Manager	-	9	13	11	*32*
Head of Department	9	11	4	2	*26*
Other Position	15	17	6	-	*38*
Grand total	**23**	**36**	**26**	**15**	**100**

Note: Number of per cent (%) of total respondents

SUMMARY OF FINDING AND INTERPRETATION

Further to the survey analysis, the affecting variables are extracted from "Level of e-commerce application to involve", "Benefits of adopting e-commerce", "Barriers of implementing e-commerce" and "Critical success factor regarding e-commerce" sections. Based on issues affecting e-commerce adoption, summarized the output in Figure 10.

The e-commerce market is still at a relatively infancy stage in Sarawak. When consider the e-commerce development, two important factors "Critical success factor" and "Barriers of implementing e-commerce" must be aware in order to have successful implementation.

Application Of E-Commerce

"Online ordering", "Electronic Advertising or Internet advertising" and "Online marketing or e-marketing" are the essential application on the internet in promoting e-commerce. This is the new channel of marketing, beside the traditional way of physically going to the store, via direct mail, phone or facsimile as media to reach everyone. SMEs in Sarawak see the prospect of this new way of doing business, by involving of these applications; they can virtually moving their products to the interested groups.

The use of the Internet for advertising or brand building has been addressed by a number of researchers. And this is one of earliest uses of the Internet for many of small organizations (Webb & Sayer, 1998). The study done by Jacobs and Dowsland (2000) also found that 30 per cent of SMEs in Wales were using the Internet for advertising and brand building.

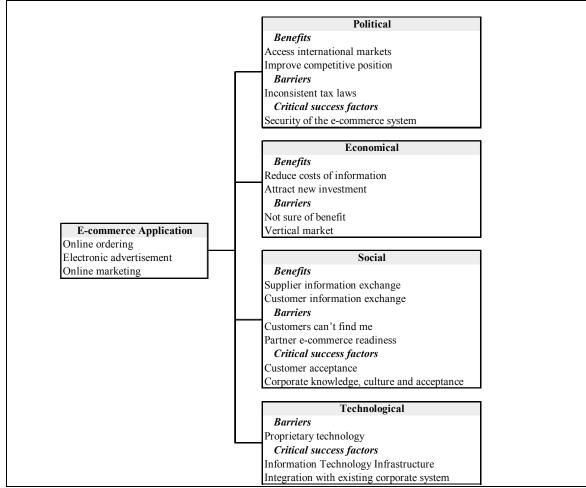
Based on their pass records, the growth rate are slow, most of them cater for local market. Currently, the business is protected. But with the globalization, neighboring countries entrepreneurs can came in with larger scale of operation and tap the market. This may become unsecured for local SMEs. if they are resists to accept the change. Gaining competitive advantages, e-commerce is a new alternative to capitalized.


Figure 5: Summary Of Variables Affecting E-Commerce

From the surveyed top ten e-commerce application, it shows that the first step towards electronic based trading is computerized their existing accounting system. It automates the routine operations and immediate response to user inquiry on transactions history. Further to the accounting system, Human resource information system to manage employees on their activities, tracking and record, it can reflect their work performance, helping manager to delegate the right job to the right most capable person. Supply chain management system to get in touch with suppliers to know the responsive and supportive from suppliers, start from product information to after sales services. This is a typical opinion from the surveyed SMEs; it is a good opportunity for systems integrator to think along this direction, further study on their business requirements, expectation and design a solution to enable them to start e-commerce.

Political Issue Of E-Commerce Development

As agreed that the government support is the most important in promoting e-commerce, it is because most SMEs still do not posses the technological capability and ability to meet manufacturing standards specified by multi-national companies and large companies. "Adoption of ICT in Manufacturing Processes" is one of the technology development program implemented by SMIDEC, one of the government agency in promote the development of SMEs. Its new ICT related grant schemes consists of:
- grant for upgrading engineering design capabilities,
- E-manufacturing grant, and
- RosettaNet standard implementation grant.

Apart from SMIDEC's grant schemes, SMEs can also avail themselves of the "Technology Acquisition Fund (TAF)" and "The Commercialization of Research and Development Fund (CRDF)" offered by Malaysian Technology Development Corporation.

SMEs are strongly agreed with the security of e-commerce are critical to maintaining successful in e-commerce. Building trust and confidence in the electronic marketplace, it is including measures to ensure the authenticity of electronic documents, and the privacy and confidentiality of personal and corporate records. Beside that, Malaysian government does aware of this treat; it passed and tabled laws to guide e-commerce, which includes:
1. Computer Crimes Act 1997
2. The Copyright (Amendment) Act 1997
3. The Telemedicine Act 1997
4. The Digital Signature Act 1997
5. The Communications and Multimedia Act 1998
6. The Communications and Multimedia Commission Act 1998

Economical Issue Of E-Commerce Development

Capable of doing business internationally and globally, it is definitely can attract new investment or new prospect to the business; cost of data transmission will going down gradually, as the internet uses increases.

SMEs, not to mention small enterprises, face increasing obstacles in accessing these new markets, mainly due to current low level of ICT awareness. Entrepreneurs and manager are currently had difficulty understanding and using the potential of the internet. Indirectly, they need that knowledge to enable them to make the strategic choices for their ICT requirements.

More than half of SMEs are considered as small scale business, they are mainly family based businesses. "Lack of qualify personnel" and "Lack of business model" become the top priorities of the barriers. They can not afford to have everything to start their business. Outsourcing becomes an alternate for them to get started without having to invest a lot of capital and minimize the risk. Most of the older SMEs are "Not sure about the benefit", they are happy with what they have, and also not interested about this new technology.

On the downside of current global economic slowdown, insufficient knowledge workers and techno-entrepreneurs with business building skills, low Internet penetration (lack of immediate sizeable market), infrastructure, perceived high cost, being risk-averse (a "wait-and-see" attitude), and lack of willingness to embrace and champion change in the organization.

The key components on the impact of e-commerce on the competitive of SMEs are:
- Cost reduction, which is in turn a measure of organizational efficiency and financial controls;
- Turnover;
- Ability to retain existing clients and win new clients, which is in tern a reflection of SMEs ability to grow market share;
- Profitability.

The globalization of markets can be considered as a positive or negative trend. In any event, it is a development that we cannot ignore. Currently, globalization of the economy is increasingly privileging the offer, the large-scale economic and financial groups, and the on-going expansion of multinationals including the medium-sized sectors.

As long as e-commerce is principally business-to-business, these trends will only consolidate. The natural evolution towards business-to-consumer will instead hopefully lead to a gradual globalization of the final demand. This would mean a return to democracy, as it were, for the entire process of globalization.

Putting efforts to work towards a final scenario of e-commerce oriented to end consumers. This in turn implies winning the trust of consumers on the one hand, and setting in place the required structures and resources to respond to the needs of expanding markets on the other.
Social Issue Of E-Commerce Development

As shown in the results of the survey, "Supplier information exchange" and "Customer information exchange" are indicate as the benefits for SMEs of using e-commerce. It is supported by Sillince et al. (1998), O'Keefe, O'Connor and Kung, (1998), Roberts et al. (2001) on document exchange with customers or suppliers.

It is believed that the best organizations to initiate e-commerce are the manufacturer or wholesaler. They can encourage the use of internet for customer supports, eliminate unnecessary intermediate layers; the manufacturer can get direct feedback about their products or services direct from their user. This provide confident for retailers to join their extranet, it is also to obtain first hand information direct from the principal office. Extranet is a place to allow its own suppliers and customers for information exchange.

Without online marketing or electronic advertisement, "Customer can't find me" become the barriers. Partners may loss its competitiveness, if "Partner e-commerce readiness" is not there.

"Customer acceptance" and "Corporate knowledge culture and acceptance" is a key success factor of e-commerce. Technology always move faster than the culture, it take years for people to change the way they live.

The social impact of the introduction of e-commerce has never been fully evaluated, but it is an issue that certainly requires attention. It appears that the exodus from traditional sectors of mediation, distribution and retail more or less corresponds to new opportunities for new professions. But it's not the same people, not at the same moment, and not with the same qualifications.

For the regions with a high level of non-employed and unemployed, this fact is a significant and justified concern, and thus a hindrance to the development of e-commerce. But this can only delay its introduction, leading to a risk of emerging from international markets. Probably we rather need to carefully monitor this shift of the labor force, decode the new professions required, and train new specialized workers with the necessary "certified" skills as part of a permanent process with regular monitoring.

Technological Issue Of E-Commerce Development

Making decision to buy a computer for office use is very easy, most of them use personnel computer at work, notebook computer are getting popular. It is not like in an old days, decision of getting a computer is just like choosing a technology to work with. Users do not have much choice, to bind themselves into a specific "proprietary technology", and they don't have much option to switch to others. With the development of personnel computer, become faster and more powerful, many office are downsizing, uses of personnel computer to handle most of the office works, interoperability provide the flexibility of getting any hardware to work with. "Integration with existing corporate system" will not create many problems, and it is seem as an important aspect of e-commerce effectiveness (Keeling et al., 2000; Melymuka, 2000; Haapaniemi et al., 2000; Hoffman, 2001) and this is the beauty of having an open system.

It is particular important for SMEs to improve business and consumer access to the internet and to e-commerce. Currently, "Information Technology Infrastructure" still not adequate to enable e-commerce, high speed broadband internet access only available at major cities of Sarawak. Indirectly, it restricts the development. At this stage, it is good to strength themselves, when the infrastructure ready, they can immediately take off and fully running e-commerce.

Prospects Of E-Commerce For Smes In Sarawak

Currently, the cost benefit of going online may still be unclear for some businesses, which may be the cause for them to hold back. However, with technology improving rapidly and becoming more affordable while simultaneously, with labor and other costs of doing business the traditional way going up, the benefits of e-business will become more evident.
Other drivers of e-commerce adoption are globalization and liberalization as well as the government's efforts and support. Services industry may adopt e-commerce more easily compared to those which involve the sale of physical goods which need to be transported to or collected by the customer.

For those in the export/import businesses, e-commerce is a means to reach an even larger pool of customers/trading partners globally. Hence, they would not be dependent on the number of shoppers in Malaysia.
For the brick and mortar companies (e.g. banks), although online customers may currently be few in number, it is an additional distribution channel which may give it a competitive advantage by offering more choices to customers. Additionally, the company can gradually steer its existing customers to this low-cost channel in much the same way banks have steered customers from bank tellers to automated teller machines.

CONCLUSIONS

This study presents a significant and important survey to examine the adoption, development of e-commerce by SMEs in Sarawak. With regards to the potential opportunities, benefits perceived barriers or obstacles to the adoption and use of e-commerce based on feedback responded from survey. This does reflect their views and perception towards successful implemented e-commerce.

The level of interest and participation in this survey has shown that they believe in the potential of e-commerce with the technology availability, advancement and government encouragement should be able to overcome the barriers and minimize the risk. Most importantly, it indicates the impact of e-commerce and creates a strong confidence in its future development or facilitates a specific e-commerce process.

Recommended Actions By Individual SMEs

Use of technology can use to increase productivity. Internet getting more and more widely available, it can be use to search for most of the require information, products or services locally or globally. Vendors must aware of it and establish their own internet website to provide for their products information, supports, receive feedback direct from customers. Encourage users or resellers to inquire or register through their web, the vendors can provide direct and faster response to the groups or individual. With this is an easier, faster and cheaper way to keep in touch and enhance customer relationship. Local vendors or manufacturers are advice to take the lead and implement it.

With the help of e-commerce, it is not a problem to support overseas clients without physically presented at their site. It is encourage doing business locally and globally. But, they have local base market to support their product. This can become a good evidence for foreign investor to believe, interested to embark and invest on. Smart investors can easily obtain information via internet or other means.

For long term strategy planning, it will have great advantage to capitalize on e-commerce or related technologies. Today, the computer network communication cost has gradually reduced; computer hardware and software are getting more powerful and cheaper. Government and related bodies are working very hard on internet security and privacy issues. Computer application already can take over routine works, which is believed to be able to process more reliable, faster and cheaper. In this case, the management can spend less time tied up with routine operation, emphasis more on productive work like how to create more customers, increase sales volumes, and so forth. Remember that the wave of the future is flexible production and flexible organizations, managers need to balance between traditional cultural values and strategic business practices in order to use e-commerce as a competitive edge in the new digital economy.

As e-commerce followers, there are a lot of successful e-commerce examples for reference. With added the unique value by local SMEs, such as hard works, able to produce world class products with limited resources, attain the right level of competitions via lowering its business overhead, sharing research and development initiatives, sharing markets and develop collaborative exchange of information and resources. These goods characteristics should maintain and incorporate it as a local context in order to compete with large organization with plenty of resources.

For a quick start without worried too much on investing, SMEs can consider outsourcing their e-commerce to external systems integrators that has the technical infrastructure and expertise in design and manage the website more efficiently. Pay small sum of money and enjoy the full features of e-commerce system. The outsourcing trend had proven to be favorable in many places in Malaysia. Alternatively, SME's could consider forming strategic alliances or having joint ventures with local systems integrators who are capable of provide such solutions to achieve strategically significant objectives that are mutually beneficial.

Recommended Actions By Systems Integrators

With study references from success implementation cases, provides a guideline and example on typical solution for local SME. Because, in today context, it is must be more focus on outcomes in terms of performance rather than on the specification of inputs.

Further study on specific industry conditions and requirements, design and tailor a suitable system in meeting user expectation, increase productivity and reduce the total cost of ownership. And this is not like the traditional

information-processing model for traditional business processes assumes a problem as given, and the solution is based on pre-specified understanding of the business environment (Malhotra, 2000).

Provide an ease of use, and friendly interface to all users, it allow user to have more confidence to use the new system. An intelligent system can identify difference user behaviors; create different user profile to fit into individual characteristics. Beside that, the English-like questions for help inquiry, create user convenience to let user freely ask any question with accumulate user experiences, the system will pick the topics related to the question output the result ordered from the most to least appropriate. To get help on specific function, setting or error fixing, make available help with step by step guide to allow user to visualize the entire process, without engage additional help from external systems support personnel. The system can have self diagnostic mechanism, allow self recovery and restore the user data and configuration. All the above mentions features is use to suggest to system integrators in reducing unnecessary support when considering design a durable user system.

Most of the bank in Malaysia is providing on-line or electronic related transaction over the internet. The real e-commerce system design must be able to incorporate it and make it not just an online ordering system. Unfortunately, most of the local e-commerce website still did not incorporate the payment capabilities.

Beside that, assist SMEs to reduce their initial start up cost by helping them to obtain grant or subsidy from government or appointed government agencies, likes TAF or CRDF, to get start with e-commerce solutions. By building up a strong business-to-business or business-to-consumer extranet to connect buyers and sellers together; can have a strong relationship to keep all parties benefits in this virtual community.

Recommended Actions By Government And Agencies

Government have important role to play in the diffusion of e-commerce among SMEs as a way to improve firm competitiveness, overcome traditional barriers and improve access to new markets.

The most significant barriers appear to be a lack of awareness of e-commerce and uncertainty about its benefits. An action suggested to Sarawak state government in collaborations with local trade associations and chambers of commerce to promote the use of e-commerce through awareness campaigns like providing information through road shows and web sites, which can be directly or indirectly influence the provision of such service. As SMEs' adoption of e-commerce are depends on their perception of the opportunities afforded by e-commerce and the relevance of these opportunities to their business. There is a need for more hands-on, customized delivery of information, assistance and demonstration tailored to specific sectors needs or specific business functions, such as international market development, supply chain management and financial management.

Knowledge of best practice, what works elsewhere, is important in formulating policies to foster e-commerce. Current policies tend to be fragmented and rather tentative. Governments must gain better knowledge of how e-commerce can help SMEs, this involve the adoption of more comprehensive and consistent policy approach to SMEs and e-commerce in partnership with the private sectors.

By promoting the development of e-commerce for SMEs, government policies should focus on the development of information infrastructure including communication infrastructure and a legal enforcement system in protecting copyright and intellectual properties. This is to enhance sharing of knowledge and information between SMEs and business partnership. Lastly, it is believe and always agree that sufficient access to information infrastructure at reasonable and affordable cost is the fundamental for e-commerce to develop.

Further Research

This study examined e-commerce application to involve, benefits, barriers and critical success factors to adoption of e-commerce by SMEs from all industry sectors in Sarawak. It identified measures which participating SMEs believe should be taken by government and others to facilitate greater adoption of e-commerce by SMEs.

There are still gaps in the understanding of the opportunities and obstacles to the adoption of e-commerce and the interplay with structural conditions specific to SMEs, such as age, size, industry sector and regional location. It is recommends an in-depth study to evaluate the benefits and barriers to the take-up e-commerce by various mentions categories.

E-mail: norazah@kms.uniten.edu.my

ABSTRACT

Electronic commerce (E-Commerce) has pervasively and dramatically affects the way firms think, operate, and compete in the market and also has already improved business value by fundamentally changing the way products are conceived, marketed, delivered, and supported in order to capture consumers awareness and interest. Understanding online consumers (i.e. the secondary stakeholder of an online firm) has become the focus of attention in the electronic business (e-business) world due to the fact that the prosperity of online companies and its survival is heavily dependent on satisfying online customers and keeping them loyal. The E-Commerce offers online consumers a wider range of benefits that cannot be underestimated, such as finding the products which are not available locally and reducing Internet users' search time for products and services. These factors have an impact on emerging trends of Electronic Commerce in Malaysia. This study focuses on providing a deeper insight into the factors that may motivate Malaysian Internet users' browsing or purchasing habits with respect to products and services. Factor analysis was performed to examine the reliability and validity of the variables relevant to Internet users' e-buying motivational factors. The implication of the study is then discussed.

INTRODUCTION

The world is moving rapidly towards Electronic Business (E-Business) and Electronic Commerce (E-Commerce) activities. It was predicted that e-commerce would generate the worldwide revenue as high as 6.9 trillion dollar in 2004, and the number of Internet users would grow as high as 765 million users in 2005 (CommerceNet, 2003). Malaysia needs to take cognisance of these trends and react quickly in order to be an active participant in the emerging electronic world and to reap the benefits of E-Commerce. However, little information is known about Malaysian Internet users' motivational factors with respect to e-buying or also known as online shopping. The study specifically focuses on Malaysian Internet users' e-buying behaviour with regards to motivational factors that supports their e-buying behaviour. Thus, this study concentrates on Business to Consumer (B2C) market.

LITERATURE REVIEW

The number of consumers buying online and the amount being spent by online buyers recorded an unprecedented global growth. It has been reported that online spending in 2002 has increased tremendously around the globe, especially during the holiday seasons. Some countries recorded positive growth of online users, with more consumer products having been purchased through the Internet. In 2002, the US Consumers spent nearly USD13.7 billion online during the holiday seasons up from USD11 billion in 2001, according to Goldman Sachs, Harris Interactive and Nielsen-Netratings. The research indicated that consumers spent more than 16 percent of their holiday budgets on online purchases in 2002, compared to 14 percent in 2001 (cited in http://www.matrade.gov.my/ecommerce/news-archive/2003/ecom-012003.htm).

The similar study found that the best performing category was books, music, and video/DVD with consumers spending more than USD3.1 billion, up 40 percent on the preceding year. Apparel spending rose 20 percent to USD2.7 billion, while consumers spent nearly USD2 billion on travel. The figures also revealed that women comprised 51 percent of the total online shopping population during the 2002 holiday season, as compared to 49 percent of males, while shoppers aged 18-24 years accounted for 17 percent of the online shopping population (cited in http://www.matrade.gov.my/ecommerce/news-archive/2003/ecom-012003.htm).

Norazah, (2001) conducted study on Malaysian Internet users adoption and behaviour on shopping online in 2001 found that there were 579 randomly selected respondents in the study, out of which 229 were Internet Shoppers; that is those who have purchased products or services through the Internet, and the dominant party were "Male" respondents. The study indicate that Internet Shoppers who own a credit card enjoyed purchasing

books/journals/magazines through the Internet, especially books at the price of less than RM 100 per item and at the similar time perceive that their level of satisfaction is higher for the item purchased through online. In most of the cases, the delivery is also made within seven days from the date of order and settled their online payments using credit card. Also, they intended to conduct repeat purchases in the near future and with a maximum amount of money expenditure is also less than RM 500 per transaction. They also reported they enjoyed browsing the Internet for "less than three hours a day" for personal purchasing reasons.

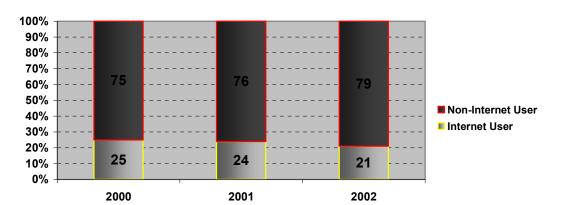
Interestingly, findings by Taylor Nelson Sofres, (2002) revealed that the penetration of Malaysians shopping online, i.e. people who bought or ordered goods and services online in 2002, was 1% of the total adult population in Malaysia. This corresponded to 3% of the Internet users in the country. Specifically, 21% of the total adult population in Malaysia are Internet users in 2002 (Please refer Figure 1). Males were the dominant Internet users, i.e. 28% of the total population, while 15% were females. The proportion of adult population that used Internet was the highest amongst the group of less than 20 years old (37%) followed by the group of 20 to 29 years olds (34%). The study found that 7% of Malaysian Internet users planned to buy or order goods or services online by the end of 2002.


Figure 1: Percentage of Population Who Are Internet Users

Source: TNS Interactive (2002). Global eCommerce Report 2002.

There is high demand for e-buying among Malaysians Internet users conducting online shopping due to E-Commerce providing enormous potential benefits that cannot be underestimated for consumers worldwide. Wider choice ranges, lower prices, and entirely new products have become made available in many product categories such as books, CDs, and travel packages, to consumers who are physically far away from the world's centers of traditional commerce. Furthermore, the Internet users could receive more attractive sales promotional offers from Internet sellers and also through individual e-mail accounts.

Electronic Commerce also enhances flexibility and convenience. Convenience is a key motive behind in-home shopping (Eastlick and Feinberg 1994). Convenience is measured by timely delivery, ease of ordering, and product display. Consumers can enjoy window-shopping on the Internet without the pressure to purchase, unlike the traditional shopping environment. Consumers are able to initiate and control non-linear searches, due to the interactive nature of the Internet and the hypertext environment. For example, Swaminathan et al., (1999) in his study found that consumers who are primarily motivated by convenience are more likely to make purchases online. Meanwhile, those who value social interactions are less interested in the Internet use for shopping and thus shop less frequently on the Internet and spend less money on E-Commerce.

The ability of online shopping to cater to social experiences outside the home, without actually leaving home, offers a distinct advantage for those unable or unwilling to venture out to physical locations, as well as offering social support (e.g. Kang & Ridgway, 1996). Kozinet (1999) prescription for marketers to follow a membership strategy as a way of rewarding loyal customers, through access to a desirable community, not only builds on these social motivations, but also suggests that membership can provide elevated status in a meaningful virtual community, thus satisfying another social motivation. Beside convenience factor and socialisation factor, time delivery is also the single most important feature that improves the satisfaction of online shopping (Kim, 2002).

METHODOLOGY

Questionnaires were developed to determine the extent of Internet users' motivation factors when browsing or purchasing through the Internet and also their personal background. Variables are chosen based on several researches done in other countries such as United States, United Kingdom (Korgaonkar & Wolin, 1999; Phau & Poon, 2000).

Respondents in this study were chosen at random at various locations such as cyber cafes, higher learning institutions' labs, and shopping malls. Out of 800 respondents, there were 579 respondents to this survey; 161 respondents from Penang, 241 respondents from Selangor and 177 respondents from Kuala Lumpur, the metropolitan city of Malaysia, out of which 334 were "Male" and the balance were "Female". They were selected from the Business to Consumer (B2C) market segment's population but only those who met the condition of having had experience in browsing or purchasing through the Internet were considered for the sample. They were drawn from different occupational categories, education, age, gender or ethnic categories but all of them fulfilled the basic condition mentioned earlier. The majority of respondents (472) in the age group of "less than 30 years old", were mostly Malays. It can be noted that in the sample, 40% of the respondents were "students" from university community such as undergraduates and MBA students. The results showed that more than half of the total respondents (63%) earned a salary of "less than RM 3,000" per month. Most of the respondents work/study in "Selangor" which represents 42% of total respondents, followed by 31% in "Kuala Lumpur". This study applied a stratified random sampling technique as a sampling method.

After the survey was administered, the data were assessed for reliability and construct validity using Cronbach Alpha coefficient (Nunally 1978). The construct validity for this research was established using factor analysis; a multivariate technique which would confirm the dimensions of the concept that have been operationally defined, as well as indicated which items were most appropriate for each dimension. Factor with eigenvalues greater than 1.00 and factor loading greater than 0.30 were considered to have adequate convergent validity (Zeller and Carmines, 1980). Data in this study were analysed using Statistical Package for Social Science (SPSS) Version 10.0.

DATA ANALYSES & FINDINGS

Cronbach coefficient alpha was used to assess the reliability of a multi-item measurement scale of the items interrelated to motivational factors. In the current study, it was found that motivational factors had coefficient alpha of 0.9478 which exceeded the recommended value of 0.70 by Nunally (1978). Thus, it is reliable for further analysis. Since the items were numerous, Factor Analysis was carried out in order to identify the underlying factors and a smaller set of important variables relevant to Internet users' motivational factors. The data analysis and interpretation of the motivation are given as follows and also stated in Appendix A.

Accessibility

The most important motivational variable when browsing or purchasing through the Internet rated by the 579 respondents was "Accessibility". "Instant access to detailed information" was eliminated from this factor because its factor loading is lesser than the fixed criteria of 0.50, causing variable 1 to comprise of ten statements with 14.548% of variance. The eigenvalue for this variable was 13.268. Out of the ten statements, the statement "easy access to wider information" was the most important statement with a loading of 0.805. The next highest statement was "faster access to latest information" which constituted 0.780 factor loading. This was followed by "the best source to search for information" with a loading of 0.668. The Internet benefit of "reduce need for intermediaries" was cited as the least important item in this variable with a loading of 0.537.

Reliability

The second variable was categorised under "Reliability" which accounted for 13.624% of variance. The eigenvalue for this variable was 3.186. The statements "web pages are visually attractive" and "convenient order cancellation process" had been eliminated from this study due to their factor loading are lesser than 0.50. Thus, variable 2 yielded with seven elements. From the results obtained, it showed that "freight charges clearly stated" was the most important element in this section with 0.814 factor loading compared to six other elements. Whereas, the second important element was "prices of product clearly stated" with a loading of 0.807. However, 0.507 factor loading was accounted in the statement "web pages are loaded faster".

Convenience

The next group of dimension is related to "Convenience", consisted of six statements with 10.546% of variance. The eigenvalue for this variable was 1.821. Shopping convenience is acknowledged to be the primary motivating variable in consumer decisions to buy at home (Gillett, 1976). It included the time, space and effort saved by a consumer and it included aspects such as an ease of placing and cancelling orders, returns and refunds, timely delivery of orders (Gehrt, Yale and Lawson, 1996).

All of the items in this variable had factor loading greater than 0.50, with the exception of one item, i.e. "faster source of getting product information" because had a loading of less than 0.50, therefore, it was eliminated from this variable. The least important statement for variable 3 was "more product variety for selection" with a factor loading of 0.501. However, the most important statement claimed by the respondents was "no crowd of people shopping", with factor loading accounted for 0.798. This was followed by 0.743 factor loading in the next statement of "no traffic jam".

Distribution

There were four statements that were loaded in this variable. The statement "no stress from customer service people" was eliminated because it did not reach the criteria of factor loading of greater than or equal to 0.50, which constituted of 9.204% of variance. Eigenvalue for this variable was 1.531.

The most important statement in this variable was "orders are delivered in good condition" with the highest loading of 0.752. This is followed by "better product return service" with a loading of 0.747. The statement "orders are delivered on time" rank in third place with 0.716 factor loading. Whilst the statement "more convenient shopping on the Internet" is the least important statement in "Distribution Motivational Factor" with a factor loading of 0.598. Most of the attributes relate to distribution pattern of online shopping, therefore this factor is called "Distribution Motivational Factor".

Socialisation

The fifth variable grouped dimensions related to "Socialisation" which accounted for an additional 3.175% of the variance. The eigenvalue for this variable was 1.375.

Of the three elements selected in Socialisation, the most important variable was that they "could have foreign friends" with a loading of 0.795. The next statement was they "could practice foreign languages by communicating with people from other countries". This also had the same factor loading of 0.795. The least important element pertaining to this variable was to "allow unrestricted discussion of current issues" which constituted a loading of 0.580.

Searchability

Variable six describes "Searchability" which accounted for an additional 1.978% of variance from variable 5. However, there were only two statements which resulted in this variable and the most important element claimed by respondents was "owning a credit card" which had a loading of 0.672. This is followed by "need few movement to find product" which had a loading of 0.586. Eigenvalue for this variable was 1.088.

Availability

The final variable in motivation was "Availability", which consisted of only one statement with 3.399% of variance. The statement "availability of products on the Internet that cannot be found locally" had a loading of 0.500. The eigenvalue for this variable was 1.065.

CONCLUSION

Factor Analysis revealed that seven important motivational variables such as accessibility (the most important variable when shop online), reliability, convenience, distribution, socialisation, searchability, and availability were extracted, which accounted for 61.402% of total variance. Of the 38 elements, 33 elements which pertain to these variables were selected. A review of the eigenvalues and factor loading indicated that all of these

variables were appropriate for further analysis and the model possessed convergent validity (i.e. the extent to which a measure correlates highly with other measures designed to measure the same construct, Churchill, 1979).

As a summary, Internet Shoppers could gain the ability to search for products not on display, gather in-depth information without taking up the salesperson's time, and even purchase or pay for products for immediate or subsequent delivery, when conducting e-buying or online shopping. Beside that, in order to retain existing Internet shoppers, order processing on the Internet should be easy for customers to do; moreover, receiving order confirmations via e-mail, including information about shipping, returns, and order tracking numbers, facilitates order-processing behaviour. If order processing is time consuming and complicated, customers will likely become frustrated and give up purchasing from e-tailer. Therefore, electronic transactions should be easy, reliable, secure, and trusted in order to attract and maintain existing users of the Internet. Such measures would increase Internet users confidence on the credibility of Internet sellers.

Moreover, by understanding consumers attitudes specifically their motivational factors toward e-buying, it can help marketing managers and online retailers predict the online shopping rate of adoption and evaluate the future growth of online commerce. It is thus important to recognize that numerous motivational factors precede attitude formation and change of consumers regarding e-buying. Future researchers should study other new variables, besides the variables mentioned in this study, such as reluctance to change, security and privacy.

ABSTRACT

This paper reports an investigation into the adoption of the Internet amongst Malaysian travel agencies as a means of exploring the likely future role of intermediary. Realizing the threats of "disintermediation", this study explores the potential threats and opportunities faced by the agencies due to the emergence of Internet-based e-commerce technology. Despite the fact that the Internet usage is limited among the Malaysian travel agencies, their traditional roles as intermediaries have not been highly affected. The emergence of the technology was not critically perceived to jeopardize their role as middlemen. In a way, travel agencies tend to believe that technology has brought them an opportunity to evolve and innovate their business strategies in the industry.

OVERVIEW

The advancement of technology in the market has transformed industry structure and the means of conducting a traditional business. The emergence of commercial facilities due to rapid development of the Internet has brought a major breakthrough in the form of modern and new ways of conducting businesses. Internet has provided businesses with a range of new opportunities and new tools such as offering cheap marketing to a wider target market, selling and customizing products and services and enabling access to a range of databases which can provide up-to-date information on market and trends (Lawrence, Corbitt et al. 2000; Turban, Lee et al. 2000). It leverages a new marketplace that matches buyers and sellers with increased effectiveness, facilitating transaction at lower cost to a more efficient "friction-free" market (Bakos 1998). The relationship between buyers and suppliers has become closer as the technology allows cheaper access to both parties. The sellers or producers are able to address the needs of individual customers to offer personalized products and services. On the other hand, the buyers can have the advantage of having the freedom to choose or buy products according to their own special needs and requirements.

The travel agency provides an interesting case for researchers to study the possibilities offered by Internet based e-commerce technology. It plays an important role as intermediaries between suppliers and customers within the travel industry by adding value to the travel products and services offered which indeed provides benefits and convenience to both parties. Apart from that, the travel and tourism industry has been greatly affected by the rapid growth of the Internet and e-business technology. It was regarded as the first area likely to do business electronically and is predicted to become a highly successful online business area.

In addition, the role of middlemen was no longer seen important due the emergence of the Internet technology. It has potentially able to replace the major functions of middlemen or intermediaries.   Hence, total elimination of the intermediaries may occur and the relationship between buyers and sellers will become closer. How serious could the role of intermediaries be threatened by the Internet technology?

The aim of this project is to investigate the perceived impact of the Internet-based e-commerce technology on the role of Malaysian travel agencies.

- The adoption of the Internet based e-commerce technology among Malaysian travel agencies will be explored.
- The potential threats and opportunities faced by Malaysian travel agencies due to the emergence of Internet-based e-commerce technology will be studied.
- The agencies' perception and attitude on e-business towards their company will be investigated.

The significance for conducting this research is to understand where Malaysian travel agencies stand with respect to the emergence of the Internet based e-commerce. Apart from knowing the level of their electronic usage, it is relevant to predict how ready and optimistic they are towards the technology used, as a mean to sustain their intermediary role in a competitive environment.

A study of disintermediation on Malaysian travel agencies has not yet been explored by researchers. This potentially allows the researchers an opportunity to explore the new dimension of IDR model in the context of the Malaysian travel industry. The outcomes are likely to generate a better understanding and predictions of the potential for e-business opportunities within Malaysian travel agency industry in near future.

This research will focus on travel agencies in Malaysia, both in the west and east regions. The travel agencies selected will be classified under "ticketing" agencies where their main role is to offer airlines bookings and reservations, and to issue international or domestic flight tickets to customers.

LITERATURE REVIEW

The elimination of middlemen or most recently known as disintermediation has become quite a debatable issue among previous researchers (Bailey and Bakos 1997, Bloch and Segev 1997, Buhalis and Licata 2001, Stamboulis and Skayannis 2002, Chircu and Kauffman 1999). The scenario of disintermediation is when an intermediary gets pushed out by other firms, or when the service it provides becomes irrelevant when other ways to do transactions become available. Due to the advancement of information technology, the needs of intermediaries are regarded less important because their role now is replace by technology which, shall radically reduced the time and cost of processing and communicating information (Chircu and Kauffman 1999).

Most traditional physical markets are often brokered by intermediaries or middlemen that facilitate market transactions by providing intermediation services (Bailey & Bakos 1997). The new innovation of technology and the transformation of new digital markets would result in the decrease of transaction cost between buyers and sellers that will ultimately eliminate the role of intermediaries. (Gates 1995, Gellman 1996). The emphasis on electronic brokerage impact was pointed out where buyers and suppliers will be able to liase conveniently, quickly and inexpensively (Malone, Yates and Benjamin 1987). The role of traditional intermediaries was threatened as the technology encourages the establishment of 'one-to-one marketing' strategies. Both market players will have the advantage of coordinating transactions; information sharing and processing directly to reduce costs and thus traditional intermediaries will no longer be needed.

Bakos' (1998) later research illustrated the impact of intermediary's roles due to the emergence of Internet-based electronic marketplaces. It shows that information technology has the ability to perform and replace the above traditional intermediaries' functions more effectively and efficiently. The author however disputed on the argument that traditional intermediaries will totally be eliminated in the near future. A study on intermediation characteristics of thirteen firms has supported the argument (Bailey and Bakos 1997). The future role of traditional intermediaries is very much depending on the nature of the electronic markets. Hence, new electronic market will not eliminate intermediaries, as their services are needed, albeit in a way that differs from their traditional role in the physical markets. It shall either allow them to maintain their traditional role of physical intermediaries or indeed be eliminated but emerge as a new role as electronic intermediaries.

Bailey and Bakos' explanation is in line with the IDR conceptual framework introduced by Chircu and Kauffman (1999). Chircu and Kauffman interpreted the terms value appropriability, where firms are capable of capturing profits consistent with innovation it offers in its marketplace. The development of new technology should be acquired together with the existing assets in order to sustain their role as intermediaries. Their interesting framework of "IDR cycle" was in line with the idea of the emergence of new electronic intermediaries or eMediaries (Bailey and

Bakos 1996, Buhalis and Licata 2001). "I" stands for intermediaries, "D" for disintermediation and "R" for reintermediation. The conceptual framework was introduced on the basis of the situation where intermediation, disintermediation and reintermediation occur in association with the emergence of the Internet. It is argued that due to the emergence of information technology, the role of traditional intermediaries where first being threatened will therefore lead them to be totally eliminated. This scenario is described as disintermediation. However, these intermediaries who have been disintermediated or pushed out from a market niche however will re-established by value adding their roles via the deployment of new technology. Hence, instead of being disintermediated, the intermediaries will emerge as new roles and functions known as reintermediation.

RESEARCH METHODOLOGY

A survey shall be conducted in this study. The population in this study consists of registered travel agencies which are classified as "ticketing agencies." There are approximately 800 agencies, and a subset of 217 samples will be selected using proportionate stratified sampling. The population will be divided into several homogeneous groups, stratified by whether there are independent agent, franchise, parent or subsidiary company (i.e. type of business). And the sampling frame will be based on the listing of registered travel agencies on MATTA website. The participants in the study are mainly holding senior positions such as Chief Executive Officer, Managing Director and Manager of the company.

Data collection techniques encompass questionnaires and structured interviews. A questionnaire is structured into several sections to reflect the objectives of the survey. The sections include company profile, knowledge on e-commerce, Internet usage and their perceptions towards e-commerce application. An interview will be done randomly on selected numbers of (major) travel agencies only in order to gain their views of the technology.

Statistical Software for Social Sciences (SPSS) will be used to analyse the quantitative data collected from the survey questionnaires. The data will be analysed mainly using a frequency and cross-tabulation analysis. Qualitative data gathered from conversations will be tape-recorded and transcribed manually using Microsoft Word. Some common words or sentences will be selected and input into table before labelling them into their own interpretation.

FINDINGS

Company's Profile

Table 1 shows that the majority of the companies in the study are the parent companies (61%). About 18% of the companies are independent and 16% are franchise companies. Only 5% are the subsidiary companies.

Table 1: Profile of Firms Surveyed

Category	Frequency	Percentage
Independent	21	18.3
Franchise	18	15.7
Parent company	70	60.9
Subsidiary company	6	5.2
Total	115	100.0

Table 2 indicates that about 72% of the companies reported to employ less than or equal to 25 workers. About 19% employed between 26 to 35 workers while about 9% employed more than 36 workers.

Table 2: Numbers of Workforce Employed

No of workforce	Frequency	Percentage
6 – 15	31	27.0
16 – 25	52	45.2
26 – 35	22	19.1
36 – 45	10	8.7
Total	115	100.0

The respondents' customers are divided into two categories; 54% are local customers and 46% are from overseas (table 3).

Table 3: Descriptive Statistics for the Major Customers

Type of Customers	Frequency	Percentage
Local	62	53.9
International	53	46.1
Total	115	100.0

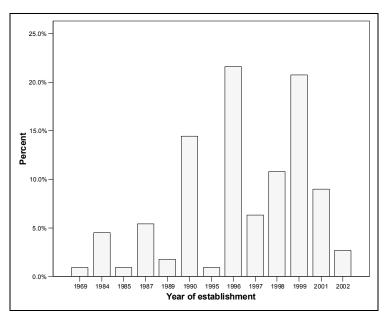
Figure 1 shows the distribution pattern of Malaysian travel agencies that were established since 1969. Based on the results, 70% of the agencies interviewed are appointed by the International Air Transport Association (IATA).


Figure 1: Year of Establishment of the Companies

Level Of Participation In E-Commerce

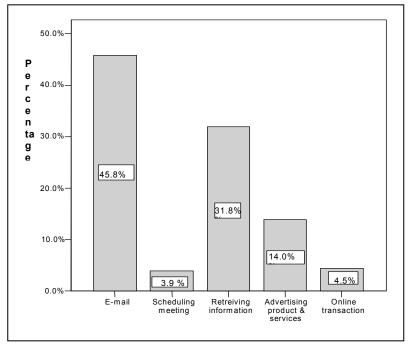
High percentage (65%) of respondents still do not have a company's website. 35% of the agencies use the Internet technology for emailing (46%), retrieving information (32%), advertising products and services (14%) online transaction/purchasing (5%) and scheduling for meeting (4%).


Figure 2: Status of Internet Usage

Respondents tend to agree with all the factors listed below due to the impact of Internet as the mean scores show less than 3.0 (table 4). Nevertheless, 58% of the respondents are neutral about the security issue due to the usage of Internet.

Table 4: Responds Toward the Impact of Internet

Statement	Strongly Agree (1)	Agree (2)	Neutral (3)	Disagree (4)	Strongly Disagree (5)	Mean
Flexible and convenient	80 (69.6)	16 (13.9)	19 (16.5)	0 (0.0)	0 (0.0)	1.46
Increased penetration of customer	7 (6.1)	63 (54.8)	45 (39.1)	0 (0.0)	0 (0.0)	2.33
Lower distribution cost	0 (0.0)	45 (39.1)	43 (37.4)	27 (23.5)	0 (0.0)	2.84
Provide good customer service	11 (9.6)	64 (55.7)	32 (27.8)	8 (7.0)	0 (0.0)	2.32
Lack of human personal touch	0 (0.0)	113 (98.3)	2 (1.7)	0 (0.0)	0 (0.0)	2.01
Security fears	0 (0.0)	32 (27.8)	67 (58.3)	16 (13.9)	0 (0.0)	2.86
Language barrier	0 (0.0)	52 (45.2)	14 (12.2)	49 (42.6)	0 (0.0)	2.97

Based on the mean scores in table 5, their satisfactory level on Internet usage are positive with high percentage on searching on information for travel (96%), easy access on company's information (83%), improving their business process (78%), creating new business opportunities (77%) and facilitating communication (74%). The least satisfactory level are reducing paperwork (33%), enhancing staff productivity (22%), extending global market reach (22%) and improving organizational task (17%).

Table 5: Satisfaction Level of Internet Usage

Statement	Strongly satisfied (1)	Satisfied (2)	Neutral (3)	Dissatisfied (4)	Strongly dissatisfied (5)	Mean
Improving business process	69 (60.0)	21 (18.3)	25 (21.7)	0 (0.0)	0 (0.0)	1.62
Facilitating communication	58 (50.4)	27 (23.5)	30 (26.1)	0 (0.0)	0 (0.0)	1.75
Easy access for customers for company information	27 (23.5)	68 (59.1)	20 (17.4)	0 (0.0)	0 (0.0)	1.94
Searching information on travel	75 (65.2)	35 (30.4)	5 (2.8)	0 (0.0)	0 (0.0)	1.39
Reducing paperwork	7 (3.9)	52 (29.1)	56 (31.3)	0 (0.0)	0 (0.0)	2.42
Improving organizational task	0 (0.0)	31 (17.3)	78 (43.6)	6 (3.4)	0 (0.0)	2.78
Enhancing staff productivity	0 (0.0)	25 (21.7)	85 (73.9)	6 (3.4)	0 (0.0)	2.86
Extending global market reach	10 (8.7)	15 (13.0)	90 (78.2)	0 (0.0)	0 (0.0)	2.69
Creating new business opportunities	10 (8.7)	79 (68.6)	16 (13.9)	10 (8.7)	0 (0.0)	2.22

Respondents are highly pessimistic about customers stop visiting their premises due to the emergence of e-business (72%) and will fully adopt e-business technology in the near future (69%). They tend to be moderate on the issues where their customers will adopt e-business in arranging their own travel plan and the danger of e-business towards their role as intermediary. However, 66% of the respondents are optimistic about the positive impact that e-business will bring to their company.

Table 6: Perceptions toward E-Business

Statement	Strongly Optimistic (1)	Optimistic (2)	Moderate (3)	Pessimistic (4)	Strongly Pessimistic (5)	Mean
Malaysian travellers will adopt e-business for travel arrangement	0 (0.0)	28 (24.3)	61 (53.0)	26 (22.6)	0 (0.0)	2.98
Customers will stop visiting premise if they have better alternative of purchasing the travel product online	0 (0.0)	13 (11.3)	19 (16.5)	83 (72.2)	0 (0.0)	3.61
E-business will endanger the role of travel agencies as middlemen	0 (0.0)	24 (20.1)	64 (55.6.)	27 (23.5)	0 (0.0)	3.02
E-business will bring positive impact / benefits to company	9 (7.8)	67 (58.3)	32 (27.8)	7 (6.1)	0 (0.0)	2.32
E-business will be fully adopted by travel agencies in the near future	0 (0.0)	15 (13.0)	22 (19.1)	79 (68.6)	0 (0.0)	3.58

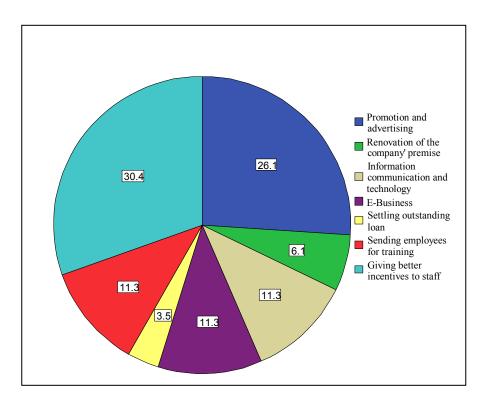
A question was asked about their main preferences on investment towards their company if they were given some budget allocation. Figure 3 shows that they prefer to give better incentive to their staff as their main preference (30%) and 26% will invest for promotion and advertisement on their company's products. Only 23% decided to invest on ICT and e-business technology.


Figure 3: Investment Preference

DISCUSSION

Currently, most travel agencies are using the Internet for sending email, retrieving relevant travel information and advertising their products and services. Positive responses were based on the way the Internet assisted travel representatives to access relevant travel information at any time and anywhere around the globe. The effectiveness of the Internet was therefore most evident in providing reliable, up-to-date and timely travel information. Hence, the purpose of using Internet was to improve their internal tasks in order to offer better products and services to their current and potential customers.

The awareness of their existing role to be eliminated by the technology was not their main concern either. Although the lacking of "human personal touch" is becoming the agencies' main concern, they still strongly believe that their role could not be totally eliminated. One main reason is because they can perceive themselves as part of the main contributors toward the growth of travel industry in Malaysia. They are highly optimistic about their role as middlemen with regards to the emergence of e-business. The flexibility in terms of giving advice, amending travel booking and accepting last minute booking services provided by the agencies are the key factors that help them to sustain their role in the industry. The flexibility of services offered by the agencies could be quite challenging if tourists or travellers were to handle it alone through Internet. Hence, due to the importance of their existing role, they are very pessimistic that travel agencies will become a pure-play company in the future.

Nevertheless, using the Internet is to enhance the flexibility and convenience of their business activities and to provide good customer service. The Internet is seen to assist them reaching a large number of potential new customers as well as to promote their products domestically and internationally.

CONCLUSION

The emergence of Internet should not be pointed out as a factor that shall jeopardize the existing role of the intermediaries. Indeed, Internet technology is a contributing factor in levelling the best practices of the travel agencies to improve their services toward customers. The "disintermediation" syndrome introduced in IDR model is not viable in this study due to the fact that the technology is continuously used by the agencies as strategic tools in

enhancing their businesses. The potential threat of lacking personal human contact should not be the main concern for not using the technology as majority of the travel agencies believe that Internet provides them opportunities as intermediary in reaching out their global target market.

Petaling Jaya, Selangor, Malaysia

ABSTRACT

This is a concept paper to explore various concerns emphasized by consumers when they purchase products and services online. Besides, it will look into the dynamics of changing retail industry, the types of online consumers, and the products sale online. Eight factors have been identified by consumers as their major concerns for any online purchase decision, from a wide range of literature reviews. They are the security of online transactions, privacy, convenience and time saved, product choice, price, product variety, online store reputation, and the availability of customer services online. This paper serves as a good foundation for a further quantitative research on the e-retailing industry.

INTRODUCTION

In the not-too-distant future, rapid advances in technology, escalating global competition, and rising consumer expectations for quality, speed of response, and customization will require companies to substantially rethink their business models. One thing is clear; the future will be substantially different from the present. Society went through dramatic changes and upheavals as a result of the transition from the agricultural age to the industrial age; the transition to the information age was accompanied by even greater change. The transition is well underway, but still remains in its early stages. The emerging consensus about the future of today's various information industries is that they will converge because they are all increasingly based on digital electronic technology. The vision revolves around the presence of an interactive broadband digital 'highway" terminating in very high-resolution multimedia display terminals in consumers' homes and workplaces. Today Internet represents a crude approximation of the capabilities and functionality that are expected to be widely deployed. It serves as a very large test bed for companies and as a "training platform" for consumers to learn new modalities of interaction and consumption. From the perspective of consumers, the primary impact of the deployment of such an infrastructure will be to ease the severe time and place constraints that are currently placed on them. "Anytime, anywhere" consumption will become commonplace.

PAST AND FUTURE MODES OF MARKETING

Figure 1:

Source: Sheth & Sisodia (1997)

Commerce today, for the most part, tend to be time and location bound. That is, transactions are constrained to occur at particular times and/or at particular locations. We are then, in the midst of a sea-change from gravitational commerce, to an era of digital commerce, which will be almost entirely free of those constraints. The future will see "anytime, anywhere procurement" coupled with "anytime, anywhere consumption".

CHANGING RETAIL INDUSTRY DYNAMICS

Retailing is expected to change with the rapid development of new online sales and distribution channels that literally can be used from anywhere and anytime. Almost every retailer is reevaluating every aspect of its operation from customer service to advertising, merchandising to store design, and logistics to order fulfillment. Online channels such as online services and the Web are impacting traditional retail business model. In the traditional model, the customer went to the store and located the product. In the online model, the retailer seeks out the customer. The success of catalog retailers demonstrates that a significant portion of consumers has embraced the reverse model: the retailer going to the consumer.

Before examining the implications of changing consumer behavior and online retailing in the existing retail business, let us step back for a moment and ask the question: Why should retailers consider the online environment as a way of doing business? The answer lies in understanding the market changes that affect retailing and that will continue to affect it in the future.

E-RETAILING

E-retailing means "a business enterprise with the capability to exchange value (money, goods, services and information) electronically" (Anderson Consulting, 1999). According to Janal (2000), several advantages of e-retailing to consumers are:

- Comparison shopping is quick and easy
- Consumers can order directly from the comfort of their home or office, 24 hours a day, from anywhere in the world.
- The stores never closes
- There are no traffic jams, no parking hassle, and no waste of time

On the other hand, online retailers also gain benefits such as:

- *Global Opportunities*: the Internet access delivers a company with an opportunity to implement highly cost-effective vehicles for positioning themselves globally. It is especially beneficial to smaller companies who want to expand their business globally, but do not have the capital and resources to do so. In addition, the Internet help ease the red tape surrounding the prospect of doing business overseas, thus avoiding regulations and restrictions that companies must follow who are physically present in other countries and who advertise in international journals (Paul, 1996).

- *Accessibility*: Company who use the Internet, increase their hours of business on a global spectrum. Instead of a typical eight-hour day, businesses have increased their opportunities by providing 24-hour access, which is important in conducting business across different time zones or internationally. Expanding access indeed increases the number and coverage of potential customers (Paul, 1996).

- *Utility*: Appropriate form, place and time utility by the Internet (i.e. giving customers the opportunity to decide what they want, where and when) result in a competitive advantage for the marketers. The Internet furnishes product and service information to current and potential customers when they want it, and hence increasing the changes of trial, purchase or repurchase (Paul, 1996).

- *Direct Communication*: As an interactive channel for direct communication and data exchange, the Internet enables focused targeting and segmentation opportunities for retailers who can more closely monitor consumer behavior (Doherty et al., 1999).

- *Cost Savings*: E-business benefits the retailers by substantial cost savings on the store, salespeople and possibly some warehousing cost. Besides, information can be rapidly changed and updated easily without any added cost, if compare to conventional catalogues which involve lots of printing and mailing cost (Doherty et al., 1999).

TYPES OF CONSUMERS

In general, consumers can be categorized into three types:

- Impulsive buyers, who purchase products quickly.
- Patient buyers, who purchase products after making comparison.
- Analytical buyers, who do substantial research before making the decision to purchase products or services.

An understanding of the consumer type allows us to delve deeper into what motivates various type of shopping. Consumer behavior, which has a profound impact on the way online systems are developed, can be viewed in terms of two questions: Why consumers do shopping and what are they looking for? As these questions imply, an online shopping experience can be valuable (accomplish something) or valueless (simply browsing). Marketing researchers over the years have categorized shopping experience into two dimensions: utilitarian and hedonic. Utilitarian means carrying out a shopping activity to achieve a goal or complete a task, while hedonic means carrying out a shopping activity because it is fun. An understanding of utilitarian and hedonic shopping can provide inside into many electronic commerce consumption behaviors that are normally not taken into account in the design and layout of electronic marketplace.

THE ONLINE CONSUMERS

Consumer demand for the Internet is a key factor that may ultimately drive widespread adoption of the Internet by retailers. Whether the consumer has access and how he or she uses or perceives Internet shopping will affect its ultimate success. Internet retailing offers a retail experience that is totally different from that of fixed-location retailing (Westland & Au, 1998). Comparison and price shopping across a greater number of sites will be easier and could be achieved within minutes. Indeed, it is common in the early part of the buying decision-making process, than for them to buy direct on the Web. They will then subsequently purchase the product through the fixed-location store or order by telephone or fax.

From a retailing perspective the use of the Internet is an elective whereby consumers require effort to access retail Web sites and select products. As a consequence carefully planned shopping online may dominate, rather than impulse shopping. Thus, Web sites that are not well designed, and which require the potential customer to browse through many screens before locating his or her chosen products, could easily deter customers from ever returning to the site. Furthermore, the medium's inability to allow consumers to touch merchandise may be problematic, as the majority of consumers prefer the social and physical interaction of 'going to the shops' (KPMG & OXIRM, 1996). The Internet also places more demands on end-users, requiring them to understand the complexity of Web site design. Additionally, the difficulties encountered in locating Web sites, searching and sorting through the Internet may also deter some consumer segments from switching to cybershopping.

According to Hoffman, Kalsbeek, and Novak (1996), those who actually but on the Web use the Internet at least once a week and are frequent Web users. On part of the gender, women are a minority on the Web, consisting of only 20 to 30 percent of the user base. However, there is a steadily growth on the Internet usage among women. A global e-commerce report by Taylor Nelson Sofres (2001) reported that 42% of Internet users and 45% of online shoppers are women. The result is aligned with a report in New Straits Times (July 4, 2001) which coded women is becoming more efficient in their Web behavior than men and are showing an increasing willingness to purchase online. Women spend less time online as they generally know what they're looking for and leave once they achieve their goal. Asian women spent an average of 12 hours online compared with 14.5 hours for men. On average, the number of women surfers across the Asia-Pacific region has been increased by 36% since January 2001.

On the other hand, Quelch and Klein (1996) stated that consumers who shop online are mostly college white males in their early thirties, earning higher than average incomes and employed in the computer, education, and other professional fields. The result closely matched the demographic profile of online shoppers in global e-commerce report by Taylor Nelson Sofres (2001), which stated that majority of online shoppers are from the age range of 30-39 years old. Even tough those who are below 20 years old are the most who surf on Internet, but they are unlikely to shop due to the non-availability of credit cards, rather than any difference in attitude and willingness.

THE ONLINE PRODUCTS

The nature of the products and the related shopping activity will govern the product groups most likely to succeed on the Internet. Basically, the major product categories of shopping include those items that are standard and require little information. Consumers purchase products ranging from food, apparel, magazine subscriptions, books, CD's, medicine to furniture, and electronics.

According to Chaffet et al. (2000), intangible products and services such as flight reservations and banking services are well suited to online trading as they are less restricted by operational logistics than tangible goods. Nevertheless, evidence from the US experience of Internet retailing indicates a preference for electronic products. Among the goods sold by the top 100 US Internet retailers, electronic products have a greater representation than other product categories. Meanwhile, banking services, books and magazines accounted for 47 percent of Internet sales in the USA. At the other extreme, clothing retailers have a comparatively low representation. This seems to suggest that that the most popular goods are those do not need to be touched or see prior to purchase (Pavitt, 1997). However, it is ambiguous to know that clothes stood as the third popular product category that was being purchase online globally in Taylor Nelson Sofres (2001) global e-commerce report, while books and music stood as the first and second accordingly. The popularity of Books and Music may due to both categories are relatively reasonably priced (low risk for the purchaser) and the homogeneity of the products (i.e. a CD is the same wherever we buy it). Then the delivery of these items is also simple and safe. Meanwhile, another research by Karakaya and Charlton (2001) showed travel related services are on the top of the list of the products/services purchased online. The travel related Web sites offer sales of airline tickets, hotel reservations, automobile rental sales and reservations.

MAJOR CONCERNS FOR CONSUMERS TO DO ONLINE SHOPPING

It is acknowledged that consumer purchases via the Internet are increasing over time, however, as suggested by Hoffman and Novak (1996), computer-mediated environments such as the World Wide Web (WWW) are not well understood, and present some unique challenges to commercial enterprise. Consumers will consider several factors when deciding whether and when to adopt the Internet as a method of purchasing for household use. As a result, it is foremost important for e-business marketers to take care of these factors which will influent consumers' purchasing decision on the Internet.

Security of Transactions

Internal network protection will be a big issue for the companies that wish to offer their services to Internet-using customers around the world. Criminals or other hackers can infiltrate company files and infect them with a virus, which is then sent to other computers to infect them. If the networks are not secure such people could also find important information about the company. It is learned that computer break-ins are not new. New security holes in the Internet are uncovered almost weekly and help to alert prospective companies and customers. As long as technology companies, software makers, banks and major credit card companies have not developed a common protocol to make financial transactions over the Internet safe, many unsolved issues still exist. The Internet needs to have a level of safety that businesses and consumers can live with.

In order to protect company data from intruders breaking into a system, companies use "firewall" computer software to protect a network from outside bad influences. Only non-destructive messages or files can pass through such a firewall, although it is fairly difficult to recognize all the "bad" files coming from the outside. There are different kinds of firewall software packages exist on the market today. Application-level security looks inside a packet and reads the data to make sure they are safe. Packet filters make sure that the package itself is satisfactory. For instance, cryptographic software can scramble the information from the sender to the receiver and a specific key is required to decrypt it. In the process of buying online, when customer types in his/her credit card number, it would be encrypted immediately. The merchant of the purchased item then passes the encrypted number to bank, which has to decrypt the number itself. The bank would then authorize the merchant to proceed with the transaction (Forcht, 1996).

Even tough firewall software could prevent unauthorized Internet traffic from entering and it is possible to make the Internet secure; however, firewall alone might not be sufficient to keep intruders out and a company should concentrate on other security aspects, too. User authentication systems are strongly recommended to allow only authenticated users to have access to a system. The development of secure ID smart cards might be a first step in the right direction to identify the user of a specific service. These cards are embedded with microchips and generate unique passwords that confirm a person's identity. Each password gets used only once and it is extremely difficult to find out such computer-created passwords. For instance, American Express used to have a

payment program called "Private Payments." This service allows cardholders to apply for a single-use credit card number; after a consumer makes a purchase, the umber is invalidated automatically (Karakaya & Charlton, 2001).

Besides, electronic cash as discussed by Rowley (1996) also played an important role in safe Internet purchasing transaction. E-cash provides another interesting option for low-cost items such as magazine. The GUI (Graphical User Icons) interface allows the dragging and dropping of icons representing stacks of coins, receipts, record books, etc. To shop on the Internet with e-cash, consumers first draw digital coins from Internet bank and then store them on hard disk. Consumers will use the coins when the vendor's software prompts for payment. Some believe that the arrival of e-cash will have a significant impact on market activity. However, for e-cash to be successful, there need to be some clear ground rules about the standards associated with the implementation of e-cash; a universal protocol for electronic money is necessary.

According to Forcht (1996), the company information security is based on three foundations:

1. *Data integrity*: A company must be sure that its data have not been changed.
2. *Confidentiality of data*: Companies have to be able to keep to themselves what customer and themselves do not want others to know, such as customer database, credit card numbers, etc.
3. *Authenticity*: Companies need to be sure that messages they receive from the Internet are from the people they claim to be.

If one of the previous mentioned factors could be worked around by the hackers, then the company is no longer secure and this can scare away the potential online shoppers.

Nevertheless, Jarvenpaa and Todd (1997) found out when people are not prompted for issues related to security, they do not think of those risks as often as issues of product value, customer service, and shopping experience (a result from the open-ended questionnaire). However, when prompted to think of the credit card concern, most participants acknowledged that it is an issue for them (a result from the structured questionnaire). Other research reinforces the finding that security issues are not stopping people from browsing and buying on-line. This was echoed by Hagel et al. (1996) who suggested that "while consumes are keen on security issues, they are willing to trade it for some kind of economic benefit". These results also consistent with a report in the New Strait Times (May 13, 1996) on the Malaysian shopping survey by Jaring Enterprise, which reported that a lack of interesting products to buy online was a common impediment to shopping than security concerns. Meanwhile, Jarvenpaa and Todd (1997) pilot study result showed that during browsing, some respondents found it annoying that they were constantly reminded that the site was secure. However, for the participants who had never shopped on the Internet, they were comforted by the message that the site was secure.

Privacy

Many Web sites ask visitors to provide information for a variety of reasons. For example, Expedia.com asks travelers to create their own profiles so that the consumers can save time in their next visit. Similarly, other online firms request data from consumers to use in their marketing activities. Sometimes, the information requested is merely names, addresses, and e-mail addresses. However, sometimes, consumers are asked to fill out lengthy marketing research surveys. The data collectors, promise consumers that they will keep the information confidential but they do not always keep their promises. Therefore, consumers are weary on providing information. In fact many consumers leave the sites without providing the requested data. (Karakaya & Charlton, 2001).

During the last decade, the Internet use by consumers has helped increase the identity theft, or using the identifying information of another person – name, social security number, mother's maiden name, or other personal data – to commit fraud or engage in other unlawful activity. As a result, it is foremost important that firms request data from consumers need to make supplying information optional and allow users to change and delete the information provided. In addition, they need to assure consumers that they will not share the information provided by consumers with other firms. A Privacy Policy statement on the Web sites will also make consumers feel more comfortable about giving information online. (Karakaya & Charlton, 2001).

According to Prabhaker (2000), every time an individual interacts with the Web, she leaves behind a rail of extraordinary detailed information about who she is, her buying habits, financial status, may be her medical records and other intimate personal details. She has very little control over who can have access to this information and what they do with it. It is unrealistic to expect profit driven businesses not to infringe on consumer privacy in an environment that makes it increasingly profitable and a technology that makes it easier than ever to collect and share personal information. A study by Tweney (1998) showed that privacy is online

consumers' biggest concern. 79 percent of online shoppers are concerned about threats to their personal privacy and 9 percent said they had fallen victim to online privacy invasion.

The fundamental problem in Internet privacy is not the disclosure of the sensitive information by itself. People will not object to companies gathering and analyzing data about their customers with the intent of serving their customers better. As long as the customers give that information voluntarily and are made fully aware as to how it is going to be used, their privacy is not being violated. The concern is, when that information is merged with several other databases owned by companies other than the one they are doing business with, then the consumer totally loses control over how that information is being used. According to Kakalik & Wright (1996), the typical consumer is on more than 100 mailing lists and at least 50 databases – the variety of information collected via cookies. For instance, it can be gainfully utilized or can be misused by bombarding people with advertising.

Convenience and Time Saved

From the Jarvenpaa and Todd (1997) open-ended questionnaire study, results showed that convenience was indeed the most salient shopping factor for their sample and the most frequent reason consumers would shop on the Internet. Shoppers emphasized the reduced physical effort, time saved, and greater convenience that the Internet could afford. However, there was complaint that it still took too many steps to find a specific item on the Internet. Hence, although virtually everyone noted the convenience of Internet shopping, they also believed it was not effortless enough. Some found the Web hard to navigate, while some were disappointed that they were not able to easily compare prices across retailers.

A good example of online grocer who has built their online business around convenience is Peapod. In general, groceries purchased through Peapod are no less expensive than groceries purchased at a local supermarket. With shipping cost thrown in, the groceries are often marginally more expensive. Peapod's target customer is the busy executive who does not have the time to shop. Groceries are delivered by courier to the customer's front door, seven days a week, at the time specified. Peapod's customers are willing to pay a little more for greater convenience. (Huff, Wade, Parent, Schneberger & Newson, 2000)

Home banking is another example of using a convenience strategy. Online banking facilities will can serve the dual purpose of reducing branch transaction costs and providing a more convenient interface through which consumers can do their banking activities such as bill payment, stock trading, money transfer etc from home. (Huff et al., 2000)

Product Choice

Offering a choice of products online that no offline merchant can possibly match is another determining factor in online purchasing. Megadepot.com, an online supply store, offers a massive selection of office supplies, software, and hardware and delivers for free anywhere in North America. Amazon.com offers more than three million books for sale, while the average conventional bookstore can stock only about 250,000 copies of books.

Price

Benjamin and Wigand (1995) study suggested that online consumer access to a broad selection of lower-priced goods was a determining factor in online purchasing. However, this is contradicted to Huff et al. (1997) study which coded products online are slightly higher than prices offline, primarily due to transportation costs and complicated local sales taxes and import duties. For instance, despite Amazon.com's 10-25 percent discount off cover prices, the price of a book shipped to the door is often slightly more than it would cost at a local bookstore.

Meanwhile, Jarvenpaa & Todd (1997) study suggested that price seemed to be the most important product value related determinant of consumers' attitude toward Internet shopping and their intention to shop in the future. Consumers would expect to see a broad array of goods competitively priced, according to Fram & Grady (1995). No "fun" technology will eliminate this need for functional benefits to the consumers.

Product Variety

In Jarvenpaa & Todd (1997) study, participants were deeply disappointed with the lack of product variety at any particular site. About a third of the shoppers expressed disappointment with the small number of products typically found among a particular merchant's offerings and limited information available about the products.

Result from the study reinforced that product variety could contribute to positive attitudes toward online shopping.

Online Store Reputation

Quelch and Klein (1996) depicted the Internet as particularly revolutionary for small and start-up firms because small companies will be able to compete more easily in the global market-space. So do consumers care who they are buying from? Jarvenpaa & Todd (1997) study's result suggested that reliability and overall reputation is very important to consumers shopping on the Web. Consumers were skeptical of stores they had never heard of, particularly those perceived to be operated by individuals. They also inquired about who regulates and monitors Web stores and whether a better business bureau existed. Thus, online store reputation is considered another factor to influent consumers' intention to shop.

Availability of Customer Service

Customer service is another major factor in online purchasing. Many industry analysts and e-commerce firms indicate that from 50 to 70% of customers abandon their shopping carts without making any purchase. The attribute reason may range from poor to no customer service. According to a recent marketing research firm, Datamonitor, 7.8% of abandoned online shopping carts in United States could be salvaged through an effective customer service. The 7.8% lost sales amounts to $6.1 billion in sales. The Datamonitor predicts that the sales lost to poor service could reach $10.9 billion this year. Most online firms have customer service and key word or product search areas (search engines) on their Web sites where customers can make inquiries. Many also have frequently asked questions sections that customers find answers to most common problems. While the frequently asked questions section on Web-sites work fine, the automated responses including automated e-mails often result in providing inaccurate information or general information that are not so useful to customers.

Companies need to develop Web sites with customer service in mind. Good Web sites have customer service centers including frequency asked questions, option of sending e-mail to customer service representatives, detailed information about products, dialog boxes where customer can submit complaints or questions. Interestingly, some online firms think they are virtual and do not provide contact information except an e-mail address. This kind of practice causes suspicion and should be avoided. Many customers still like to phone companies to voice their complaints or discuss problems. Including eight hundred numbers and names of individuals to contact is certainly a plus today (Karakaya and Charlton, 2001).

At the same time, Huff et al. (2000) shared the same view. They mentioned that the keys to customer service in the world of Internet business are responsiveness and "high touch". If everything else works perfectly, the need for customer service, in principle, should be minimal. One common scenario where fast response is necessary involves entering a credit card number. First-time online shoppers often want extra assurances that they won't lose their life saving when they click the "purchase" button. Having a clearly displayed 1-800 number they can call for reassurance, right at that point on the screen, can go a long way toward calming such fears. But if consumers do call and are made to wait for a long time, that may be worse than no number at all.

There are millions of sites on the Internet each competing for cyber loyalty and many companies are working hard to produce "sticky" sites. Stickiness is measured by the number of minutes visitors stay at a site and the frequency with which they return (Crockett, 2000). To do this they must add value to the consumer's experience. Internet services have to be tailored to meet customers' needs. Satisfying the customer is no longer sufficient. Firms have to meet customers' expectations of having an enjoyable experience when they deal with a particular organization. If not, customers will go elsewhere to a competitor who is only a click of the mouse away (Muir & Douglas, 2001). Meanwhile, Karakaya & Charlton (2001) mentioned about the good product delivery and returns policy can boom the product sale online.

According to Bitran & Lojo (1993), the quality of service depends not only on offering products that meet customers' needs and delivering them efficiently, but also on creating an atmosphere and overall experience that is satisfying. Hoffman and Novak (1996) argued that the Internet storefronts provide greater consumer control and are more accessible, flexible, and se-stimulating than traditional retail stores.

In Jarvenpaa & Todd (1997) study, participants were dismayed by the difficulties in trying to do goal-directed shopping and locate specific products or specific merchants. They were also frustrated by numerous broke or inactive links. They thought the store directories were misleading, making them expect one thing but providing another. The participants frequently got lost in the aisles of the malls. A common feeling was, "I would already be on my way if I were in a real mall." Then, even the participants who stumbled across items that were novel

and interesting, much the same way that that they do when window shopping, found that many sites provided limited support for the buying process. Online merchants had not considered the needs of consumers for information about policies related to returns, shipping charges, product guarantees, and the like. In some instances, to place an order the customer was expected to remember product codes, calculate taxes, and add in shipping costs – all of the things that participants believed computers should do for them. The result suggested that participants found customer service to be largely nonexistent on the Web. In summary, Jarvenpaa & Todd (1997) study indicated that customer service did influence participants' intention to shop online. Thus, the lack of information on company policies with respect to pricing, returns, delivery times, and guarantees did temper participants' enthusiasm for completing a commercial transaction on the Web.

CONCLUSION

Doing business on the Internet will become even more important in the future. More companies will have access to the Internet and, with a reduction in communication prices, more customers will come to the Internet as well. The Internet offers tremendous possibilities and could, in the long run, outperform conventional distribution channels. It is very easy to get connected to the Internet and people can surf and shop the Internet 24 hours a day, if they want to. The Internet offers an excellent way to get in touch with the customers on a one-to-one basis. According to Forcht (1996), better technologies will help companies to represent themselves better and sell more products. Muir & Douglas (2001) further add that IT skills alone may not be sufficient to cope in such a dynamic environment. Management and general business skills may also be required. Despite some barriers, individual and household consumers are making more and more use of the Internet when purchasing services and products. A key question raised is whether the e-retailers have the appropriate skills in place to deal with such transformations in the marketplace and do they concern about the determining factors that influent consumers online purchasing behaviors, from the consumers' point of view.

ABSTRACT
The aim of the article is to show the findings of the factors influencing the adoption of e-commerce among small and medium-sized chalet operators in Peninsular Malaysia. The principle objective of this study is to investigate the factors influencing the adoption of e-commerce among small and medium-sized chalet operators. Further, to identify the readiness of small and medium-sized chalet operators in dealing with e-commerce activities. Two approaches were undertaken in the study. An extensive library search was carried out to obtain journals, master thesis and doctoral dissertations. The Logistic Regression was applied to test the hypotheses because the dependent variable (e-commerce adoption decision) which was dichotomous in nature.

INTRODUCTION

The tremendous growth of the Internet, has led to the increased number of consumers and firms involved in the on-line economic global marketing. Indeed, the development of technology has changed the market environment permanently (Fojt, 1996) and it is up to the Small and Medium Tourism Enterprises (SMTEs) to regard them as opportunities or challenges to ensure their survival and their capability to do business in the international market. Moreover, the challenge brought up by the new electronic commerce (e-commerce) economy will revolutionize various sectors in the Malaysian economy, such as the tourism industry. E-commerce usage in this context refers to "the sharing of business information, maintaining business relationships and conducting business transactions by means of Internet based technology".

Tourism Industry in Malaysia

In Malaysia, tourism is the third largest foreign exchange earner after manufacturing and oil palm through its vast arrays of tourism products. Tourism is considered to be the contributors of Malaysian economic activities. The vast array of tourism products offered by Malaysian tourism industry include attractive hills and island resorts, international-class shopping facilities, eco-tourism, agro-tourism, homestay programmes, cultural and heritage tourism.

The number of international tourist arrivals and receipts can be used as a measurement to measure tourism industry's contribution towards the Malaysian economy. The following Table 1 demonstrates the number of tourist arrivals and the total tourist receipts in year 1995 and 2000.

As depicted in Table 1, international tourism arrivals and receipts have increased tremendously. The number of tourist arrivals, for example, has increased from about 7.5 million in 1995 to about 10 million in 2000. Similarly, the total tourist receipts has also increased from RM 9,174.9 million in 1995 to RM 17,335.4 in 2000.

Table 1: The number of tourist arrivals and receipts from international tourism

Indicator	1995	2000
Number of Tourist arrivals ('000)	7,469	10,221
By Country of Origin (%)		
ASEAN[1]	73.5	70.3
Japan	4.4	4.5
China	1.4	4.2
Taiwan	3.9	2.1
Hong Kong SAR	2.0	0.7
India	0.4	1.3
Australia	1.8	2.3
United Kingdom	2.2	2.3
USA	1.3	1.8
Others	9.1	10.5
Total Tourism Receipts (RM million)	9,174.9	17,335.4

* Source: The Eight Malaysia Plan 2001-2005

Taking into awareness the importance of domestic tourism, the government has encourage aggressive promotional activities under the theme *Cuti-cuti Malaysia* with the aim of encouraging domestic travel and reducing currency outflows. The number of domestic tourism trips increased by 89.9% at 15.8 million trips in 1999 compared with 8.32 million trips for the period August 1997 to July 1998. The number of domestic guests also increased by 46 % to 1.02 million in March 2000 compared with 698,000 in March 1998. The rapid improvements in the transportation system provided faster and easier access to tourism destinations, which facilitated the increase in domestic tourism.

METHODOLOGY

A survey instrument (questionnaire) was formulated to obtain feedback from *Small and Medium-sized Chalet Operators* assessing their adoption of doing business over the Internet. Table 2 shows the mapping of questions in the survey instrument, which consist of four parts.

Table 2: Mapping survey of questionnaire

Part A	Company's information such as number of employees, rooms and others related information were asked to the respondents
Part B	Information regarding the status of Internet usage such as e-mail, website, and others were asked as measurements of dependent variables
Part C	This section is measuring adoption factors that influencing *Small and Medium-sized Chalet Operators* towards implementing e-commerce in their business. Questions asked are adopted from previous study done by Kendall et al. (2001), with some modification and addition to suite the objective of this study. The items is measured using a five point Likert scale from the range of strongly disagree to strongly agree
Part D	This section is modified and adopted based on Kendall's study (2001), which was formulated based on the possible levels of e-commerce discussed in European Commission (1998). Respondents are needed to answer based on the scale provided to indicate how soon they are willing to adopt different stages of doing business over the Internet and e-commerce, as well

Data Collection

The survey questionnaire was disseminated to Small and Medium-sized Chalet Operators by mail and a few *enumerators* . In order to encourage participation, an endorsement letter from Ministry of Cultural, Art and Tourism (MOCAT), a cover letter explaining the purpose of the study and a reply self-address returned envelop were enclosed. A total of 59 questionnaires were received and collected within a period of six months with a 29.5% of response rate. However, only 56 questionnaires were classified as valid.

General profile and summary statistics

Several demographic characteristics of the respondents were discussed and shown in Table 3. A total of 67.9 percent (%) of the small and medium-sized chalet operators involved in this study were located in Pahang and

10.7% in Terengganu. Perak, Kedah and Selangor each had 5.4% of the sample population. Only 3.6% were located in Johor and 1.8% in Kelantan.

In terms of categorisation, most of the respondents were located in the island area (69.1%), followed by the beach area (23.6%) and hill area (3.6%), while the city and lake areas each had 1.8% of the sample population. The number of rooms available and the extent of labour (employees) employed by the chalet operators were used as the measurement to determine the size of the small and medium-sized chalet operators, whether they were small, medium or large. The majority of the respondents (68.6%) reported to employ less than 10 employees in their resort. About 15.7% employed between 10 to 20 employees, 2.0% between 20 to 30 employees, 3.9% between 30 to 40 employees, and 9.8% employed more than 40 employees.

Out of 56 chalet operators involved in this study, 12.5% of them have less than 10 rooms. Most of them (30.4%) however, have from 11 to 20 rooms. Meanwhile, 26.8% have between 21 to 30 rooms and only 7.1% offered between 31 to 40 rooms. About 23.2% offered 41 to 50 rooms. The result also showed that most of the small and medium-sized chalet operators were found to be established in the nineties (1991 to 2000), totaling 56.6%, whereas 24.5% were established between the year 1981 to 1990 and 9.4% before 1981 and between the years 2001 and 2003.

Table 3: Sample characteristics

Location	Frequency	Percent(%)

2000 to 2003	5	9.4

Based on the figures presented in Table 4, a high percentage of small and medium-sized chalet operators (41.56%) had reported to own only one unit of PC. About 18.9% owned two units of PCs, while 5.7% of them reported to have three and four units of PCs. Those with five, six and eight PCs constitute 3.8%, 1.9% and 1.9% respectively, followed by those with ten PCs with 3.8%. None of the respondents have seven or nine PCs, while 17.0% of them reported not having PCs.

The level of participation in the Internet usage, covering the Internet connection, e-mail, website, on-line chalet reservation, and on-line payment to/from suppliers/customers, will be used as the measurement to measure participation in e-commerce. Table 5 provides the status of Internet usage among the respondents surveyed. Most of the respondents reported to have Internet access, e-mail, and website with 68.5%, 69.2% and 64.2% respectively. Meanwhile, 56.9% of them reported to be involved in on-line chalet reservation and 21.6% of them are involved in receiving electronic payment from their customers. None of the respondents were involved in electronic payment to suppliers.

Table 5: Status of Internet usage

Items	Frequency	Percent (%)
Internet access	37	68.5
E-mail	36	69.2
On-line chalet reservation	29	56.9
Website	34	64.2
Payment from customers	11	21.6
Payment to suppliers	0	0

According to Table 6, most of the respondents began to have Internet connection in year 2000 with 30.3%, followed by year 2001 and 1999 with 18.2% and 18.2% respectively. A few of the respondents began to have Internet connection prior to 1999.

Table 6: Year of having Internet connection

Year	Frequency	Percent (%)
1999	2	8.7
2000	3	13.0
2001	2	8.7
2002	3	13.0

Respondents who have Internet access were also asked the reason why they use the Internet (As in Table 7). "Providing customers information" was the main reason at 61.5%, followed by "Communication within/outside the company" at 48.1%, and an effort to "Enhance the image of the company" at 46.2%. "Getting information from suppliers" and "Buying and selling products and services" were also among the reasons for having Internet connection with 36.5% and 34.6% respectively. Table 7 summarised the reason for using Internet.

Table 7: Reasons of using Internet

Items	Frequency	(%)
Communication within/outside the company	25	48.1
Getting information from suppliers	19	36.5
Providing customers information	32	61.5
Company's image enhancement	24	46.2
Buying and selling products/services	18	34.6

This study also found that 6.9% of the respondents had launched their own website in 2003, 1999, 1998 and 1997. The majority of them had launched their website in 2001 with 31.0%, followed by 20.7% and 17.2% in 2000 and 2002 respectively, as Table 8 demonstrates.

Table 8: Year of launching website

Year	Frequency	Percent (%)
1994	1	3.0
1996	1	3.0
1997	1	3.0
1998	3	9.1
1999	6	18.2
2000	10	30.3
2001	6	18.2
2002	4	12.1
2003	1	3.0

Among the five items constructed to measure the reason of having a website, most of the respondents ranked "Provide information to customers" as the main reason at 60.8%. Those who ranked "Advertisement", "Explore new model of business", and "Gain competitive advantage" constitute 51.0%, 47.1% and 44.2% respectively. "Pressure from competitors" was ranked as the lowest with 8.7%. The summary of the results as ranked by the respondents and mean value of each statement is summarised in Table 9.

Table 9: Reasons of having website

Items	Frequency	Percent (%)
Gain competitive advantage	23	44.2
Explore new model of business	24	47.1
Pressure from competitors	11	21.6
Provide information to customers	31	60.8
Advertisement	26	51.0

Logistic regression

The logistic regression technique was applied to test the research hypotheses. The significance of the hypothesized independent variables were examined to determine support for the hypotheses.

The model for Chi-Square shows a value of 12.598, which is the difference between the initial -2 log likelihood (75.837) and the final -2 log likelihood (63.239). The model (Chi-Square = 12.598; Significance = 0.027) indicates that the logistic regression model is significantly different from a perfect model, which correctly classifies all respondents into their respective groups: adopters and non-adopters. The goodness of fit statistics was measured to test the goodness of fit of the model using the observed and predicted number of events, by using the Hosmer and Lemeshow test. The goodness of fit is 7.536, distributed as a Chi-Square value, with significance of 0.375. This study found an insignificant probability, which indicates that, the expected and observed values are close, in-turn implying that the model is a good fit.

Therefore, the model does appear to fit, confirming the change in -2 log likelihood test (test of model). In terms of measurement for the accuracy of prediction, the overall predictive accuracy in this model is 75.0%, which can be considered as good. Even though the model fits the data and is relatively high in its predictive accuracy, the relationships between variables are low (Cox & Snell = 0.201; Nagelkerke = 0.272). Table 10 demonstrates the figures of findings.

Table 10: Model Fit Statistics

- 2 Log Likelihood		63.239	
Goodness of Fit		7.536	
Cox & Snell – R^2		0.201	
Nagelkerke – $R^$		0.272	
		75.0	
Percentage correct in classification table			
	Chi-Square	df	Significance
Model	12.598	5	0.027
Block	12.598	5	0.027
Step	12.598	5	0.027

The values in the equation were obtained from the output of the logistic regression.

The original value is in the log of the odds, or logit. Therefore, the beta coefficient (β-coefficient) is the effect of a one-unit change in an independent variable on the log odds. In organizational readiness, for instance, the effect is to increase the log odds by 0.018. As the individual factors, the significance for inhibitors was significantly

different from zero (less than the α-value of 0.05). Meanwhile the significance for the other four variables was not significant.

The first hypothesis was "H_1 = The greater level of benefits perceived by small and medium-sized chalet operators, the more likely they will adopt e-commerce". The significance value for perceived benefits was 0.211, which is higher than the α-value of 0.05. Therefore, H_1 was rejected and there is no significant relationship between perceived benefits and adoption decision. The second hypothesis was "H_2 = The greater level of organizational readiness, the more likely they will adopt e-commerce". This hypothesis was rejected because the significance value for organizational readiness was 0.829, which is greater than the α-value of 0.05. The third hypothesis was "H_3 = The greater level of external pressure, the more likely they will adopt e-commerce". The relationship between external pressure and adoption was found to be insignificance because the significance level (0.998) was higher than the α-value (0.05). The fourth hypothesis was "H_4 = The greater level of inhibitors perceived by small and medium-sized chalet operators, the less their involvement towards adopting e-commerce". This hypothesis was deemed acceptable because the significant value is 0.014, which is lower than the α-value. Therefore, there is a significant relationship between adoption and inhibitors.

The tested hypotheses explained significant proportions of the variables representing factors that motivate and inhibit the adoption of e-commerce. Table 12 contains a summary of the hypotheses tested.

Table 12: Summary of the hypotheses tested

	Hypothesis	Rejected or Accepted
H_1	The greater level of benefits perceived by small and medium-sized chalet operators, the more likely they will adopt e-commerce	Rejected
H_2	The greater level of organisational readiness, the more likely they will adopt e-commerce	Rejected
H_3	The greater level of external pressure, the more likely they will adopt e-commerce	Rejected
H_4	The greater level of inhibitors perceived by small and medium-sized chalet operators, the less their involvement towards adopting e-commerce (Inhibitors to adopt e-commerce were found to be significant. This findings support the view that small and medium-sized chalet operators have been slowed to embrace e-commerce due to a number of obstacles to e-commerce application, such as security concern (mean value 3.25), difficulties with current practice (mean value of 3.04), lack of financial resources (mean value of 2.84) and lack of guidance (mean value of 2.95)).	Accepted

RESULTS AND DISCUSSION

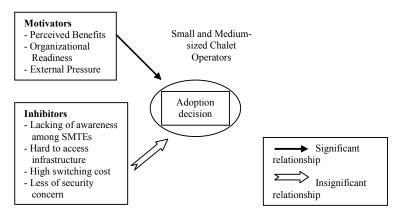
This study clarified the relationship between the dependent (e-commerce adoption decision) and independent variables in the model presented in Figure 1. A significant relationship was found between inhibitors and adoption decision, as represented by the arrows in Figure 2.


Figure 2: Relationship between dependent and independent variables

As for the factors related to motivators of e-commerce and adoption decision, perceived benefits, organisational readiness and external pressure were found to be insignificant. Even though a number of previous studies have reported that perceived benefits, organisational readiness and external pressure have an effect on the adoption

decision of new technology (Mehrtens et al., 2001; Kendall et al., 2001; Poon and Swatman, 1999; Premkumar et al., 1999; Iacovou et al., 1995; Cragg and King, 1993). Iaocovou et al. (1995) for example, showed a strong relationship between adoption and perceived benefits. Meanwhile Premkumar et al. (1999) found that perceived benefits as the only significant variable to discriminate adopters from non-adopters in the communication technology adoption decision. Besides, they also discovered that top management support (items discussed under organizational readiness), size and competitive pressure (items discussed under external pressure) as an important determinant for the adoption decision.

Theoretically, perceived benefits, organizational readiness and external pressure has a positive relationship towards adoption decision. This study, however; fails to find any significant relationship between those variables with the adoption decision. The differences exist due to several reasons.

Previous research on adoption decision have been on different subjects, such as rural communities in a mid-western state in United of States (Premkumar et al., 1999); Information System (IS) managers (Chau and Tam, 1997); suppliers to British Columbia (BC) government (Iacovou et al., 1995); owners and managers in the automobile industry (Akkeren and Cavaye, 1999); members of the Association of Small and Medium Enterprises of Singapore (Thong and Yap, 1999; Kendall et al., 2001); small business in Netherland (Walzuch et al., 2000); and small business in Australia (Poon and Swatman, 1999).

In comparison, this study sought to investigate the chalet operators in Tioman Island, which was not done before and used a combination of theoretical models, as presented in Figure 1. The findings in this study can be similar to or differ from previous studies in several aspects. This study differs from previous studies in the following aspects: (1) it investigates subjects in the tourism industry; (2) subjects being studied have a different culture and social system; and (3) relatively small respondents.

Specifically, this study differs from Thong and Yap (1996), who were concerned with factors that affect IT adoption, such as CEO innovativeness, attitude towards IT adoption, competitive of environment and information intensity, while this study was concerned with all the sources being discussed by Tong and Yap (1996) and has included more variables to support the study.

This study differs from Kendall et al. (2001), who had utilised a portion of Rogers' Model of Innovation as their framework, whereas this study has combined several aspects from Rogers' model and others research models.

This study also differs from Mehrtens et al. (2000), who identified similarities and differences between Internet adoption and EDI adoption in small firms. They used Iacovou's theoretical framework as their model, whereas this study was done to identify the factors that motivate and inhibit e-commerce adoption in Small and Medium-sized Chalet operators.

Tiessen et al. (2001) only investigated the reason why firms use e-commerce by relating two types of environmental variables (market changes and industry norms) and three firm factors (technical capability, cultural capability and firm size), whereas this study investigates multi-dimensional reasons why firms make a decision to adopt or not to adopt e-commerce.

This study also differs from Chambers and Parker (2000), in using a more comprehensive model incorporating the factors that are motivating and inhibiting rural small businesses' use of web commerce. Meanwhile this study did not include individual factors, for example education, age, personal traits, time and skill, cultural aspects and task factors, as Chamber and Parker investigated in their study.

From the tourism studies perspectives, this study differs from Buhalis and Main (1998) who worked on small and medium hospitality organisations, whereas this study worked on chalet operators (SMTEs). In addition, Buhalis and Main (1998) did explore the factors determining the adoption of IT's by examining the stakeholders of small hospitality organisations, as well as the push and pull factors they exercise. Meanwhile this study is focused to determine the factors that motivate and inhibit the adoption decision.

The inconsistencies between this research with previous research have led us to the conclusion that a socio-cultural issue might give an impact on the adoption decision. Culture, according to Assael (1987) refers to the norms, beliefs and customs that are learned from society and lead to common patterns of behaviour. Different cultures influence how people may perceive certain things, what they value and how they interpret the graphical images and lines of text they encounter on a website. Therefore, people from different countries may react in different ways because they are physically different, and have different climates, economics, religion and history (Williams, 1991).

This view is supported by Dr Mahathir Mohamad, (the Malaysian Prime Minister, 1996)

> *"The tendency has always been to forget culture entirely when dealing with technology and development. The result is that importation of foreign technology and concepts of development have been disappointing to a good many developing countries. The interplay of technology, culture and development, while it can be complementary, can also tear a society apart if not fully appreciated, integrated and guided. For a society, technology transfer is not possible or at least not easy to achieve. The point that is being made here is that before technology can be successfully transferred or while it is performed, the cultural resistance must be overcome. This can only be done if there is understanding of the culture of the transferee community, or better still, the difference in culture of the transferors and the transferees".*

According to Aljifri, Pons and Collins (2003), the prevalence of the English language in Internet technology can also be a reason for companies especially where English is not the predominant language, to be excluded from participating in e-commerce. Moreover, converting to English language would mean giving up part of the organization's culture (Bonits and Decastro, 2000).

The difference in results may also be due to the uncertainty avoidance factor. Uncertainty avoidance factor refers to the degree to which the members of a society feel uncomfortable with uncertainty and ambiguity (Nobes and Parker, 1998). Malaysian Small and Medium-sized Chalet operators might be afraid to try and adopt something considered as new to their business culture, even though benefits of adopting new technology such as e-commerce have been constantly advocated by previous researchers. The uncertainties about the benefits can be gained in the future; keen competition and demand uncertainties might also be a reason for the Small and Medium-sized Chalet operators to simply take a wait-and-see attitude (Chau and Tam, 1997). Therefore, if the first adopters were to think only of their own immediate benefits, rather than about how they might eventually benefit or how their organisation might benefit, no one would adopt and the diffusion process of the innovation would never begin (Rogers, 1995).

In addition, Rogers (1995) noted that computer related innovations could create uncertainties in an organization and uncomfortable states in a system that often leads to resistance to the technology. Gerwin (1988) had identified three different types of uncertainties in computer-aided manufacturing technologies. These are (1) technical uncertainty; (2) financial uncertainty; and (3) social uncertainty.

From a different perspective, the result of this study is consistent with Chau and Tam (1997), whom worked on the factors affecting the adoption of open systems. Their study also failed to find a relationship between the external environment context and perceived benefits with open systems adoption.

Conversely, inhibitors to adopt e-commerce were found to be significant. This findings support the view that Small and Medium-sized Chalet operators have been slowed to embrace e-commerce due to a number of obstacles to e-commerce application, such as security concern (mean value of 3.25), difficulties with current practice (mean value of 3.04), lack of financial resources (mean value of 2.84) and lack of guidance (mean value of 2.95). Technophobia be can also regarded as a reason why Small and Medium-sized Chalet operators refused to be involved in e-commerce activities (Paraskeras and Buhalis, 2002). The findings were somehow consistent with the research done by Paraskeras and Buhalis, (2002); Ankar and Walden, (2001), in which they found that inhibitors had association with the e-commerce adoption decision

SUMMARY AND CONCLUSION

The study investigates factors that motivate and inhibit Small and Medium-sized Chalet operators adoption of e-commerce. The principal objectives of the study are to determine the extent of usage of the Internet facilities and e-commerce among Small and Medium-sized Chalet operators. This study proved that inhibitors to adopt e-commerce were found to be significant. This findings support the view that Small and Medium-sized Chalet operators have been slowed to embrace e-commerce due to a number of obstacles to e-commerce application such as security concern, difficulties with current practice, lack of financial resources and lack of guidance. However, the limitations of this study which affect the results include several aspects, which give pointers for future research in this area. Firstly, data were obtained from chalet operators through mail questionnaires, and therefore the number of responses can be questioned. The major drawback of mail questionnaires is the low response late and any doubts the respondents might have cannot be clarified. The relatively small sample size (response rate = 29.5%) is due to the disadvantage of the mail questionnaire method, which has limited generality for the whole tourism industry Nevertheless, the results can form a benchmark, the basis to which to improve future findings. Secondly, there were insufficient resources available; especially in the Malaysian context had affected the development of a more precise theoretical framework for this study. Thirdly, the number of chalet operators was limited because many of them have ended their own business. This problem maybe was caused by the very windy and unstable climate which generates big waves. Finally, this study was

largely constrained by time and money, so it was not possible to study more variables such as family-oriented businesses, market uncertainties and complexity of IT infrastructure.

This research was exploratory in nature, and only intended to identify factors that are motivating and inhibiting the e-commerce adoption decision. Therefore, this research supporting that inhibitors is the major factors of why Small and Medium-sized Chalet operators reluctant to adopt e-commerce. More extensive research is required to examine these factors closely. Specific future research possibilities arising from this research are:

i.   Conducting more extensive and representative qualitative study to determine the extent to which the factors that are really inhibiting Small and Medium-sized Chalet operators adoption of e-commerce. Therefore, the result of future findings will suggest to the government, for example, to more focus towards decreasing inhibitors factors as a method to increase Small and Medium-sized Chalet operators involvement in adopting e-commerce.

ii.   Socio-cultural issues (cultural and language differences) and their impact on Small and Medium-sized Chalet operators commitment and adoption decision can also be a part of future research;

iii. Other factors such as family oriented businesses, market uncertainties, complexity of IT infrastructure and information intensity can also be researched further and added to the theoretical framework.

iv.   Determining whether the factors identified are also applicable in other contexts, such as in travel agencies and also whether they apply to Small and Medium-sized Chalet operators generally; and

v.   Undertaking research focused on other Small and Medium-sized Chalet operators in Asian country, such as Thailand and Philippines. Hence, the result in Malaysia can be compared to other Asian country in order to determine how the inhibiting factors can be addressed and better facilitated.

The major findings of the study include that Small and Medium-sized Chalet operators experienced inhibitors as obstacles from adopting e-commerce. On one extreme, perceived benefit, organizational readiness, and external pressure failed to prove that they are the most important factors motivating e-commerce adoption by Small and Medium-sized Chalet operators. They can contribute by making a full list of all the operating chalets on the website in order to attract tourists from all around the world. Moreover, the facilities and infrastructures should be upgraded to improve the security and safety of the tourists. In addition, training should also be provided to the chalet operators in IT field in order to draw attention from the government where the government can provide loan without or with lower interest to the chalet operators. Here, good accommodation and communication through IT usage can attract many tourist. This study also suggested major recommendations for the Malaysian government, especially in the tourism sector and provided directions for future research.

Banking in the Era of Globalization:
Why Bankers should Focus on 'Relationship Banking' with their Small Business Customers?

Mohd Yusop Mohd Jani

INTRODUCTION

Forces of globalization fuelled by advances in information technology and the growing financial sophistication of customers have changed the banking environment during the last decade. This has resulted in intensified competition among the existing and new players in the market place. The key to success or even surviving in an increasingly competitive environment requires an increasingly deeper understanding by banks of this environment and to capitalize on opportunities associated with it. Banks are now finding themselves in the situation whereby they are having to work harder to retain customers that they once had the luxury of taking for granted. One of the strategies is for the banks to establish and maintain strong relationships with their customers. Seybold (2001) argues that building deep relationship with customers is vital to ensure the maintenance of future earnings. Banks need more effective approach to an understanding of customers and their needs. However, one increasingly important segment of the market, which arguably has not been given enough attention, is the small business sector. The small business sector is now a significant and growing market segment and its importance to the economic development of a nation is well established. The banks may miss the opportunity of an emerging lucrative market if they fail to recognize the potential profitability that this sector provides. Studies by Kolari, Berney & Oui (1997) and Dunkelberg (1997) revealed that, on average, banks earn higher profit margin on small business loans than on other assets. Furthermore, if banks focus mainly on large customers, this could lead to smaller margins. These customers have a readily available source of funding through the capital market, and hence the additional negotiating advantage. As a result, large business customers may no longer provide the profit potential they once did. Therefore, the ability to attract and retain small business customers should be in the long-term interest of the bank.

This paper reports on a study conducted among small business owners on their business relationships with the banks. The purpose is to generate an understanding of the nature of bank-small business customer relationships in Malaysia. The findings of the study will provide banks with information that may put them in a better position to understand the needs of their small business customers.

LITERATURE REVIEW

WHAT IS A SMALL BUSINESS?

There is no commonly held definition of what constitutes a small business. A business may be regarded as 'small' if it has certain economic or management characteristics. For example, Watson & Everett (1993) define it as a business in which one or two persons are required to make all the critical management decisions in finance, accounting, personnel, purchasing, processing, servicing, marketing or selling without the aid of internal specialists and with specific knowledge in only one or two functional areas. Storey (1982) categorizes a small business as that of having a small market, being managed by the owners who are legally independent in taking their decisions. In Malaysia, various criteria have been used to classify the business for the purpose of allocating technical or financial assistance. The Small and Medium Industries Development Corporation (SMIDEC), an agency under the Ministry of International Trade and Industry (MITI) defines it as a manufacturing enterprise with an annual sales turnover of not exceeding RM25 million or as a business enterprise which employs up to 150 full-time workers (Smidec, 2002). The World Bank study on Malaysian industries considers the small business enterprises as those employing between 5 to 49 full-time employees, and the medium-sized enterprises as having between 50 to 199 employees (UNIDO, 1990).

For the purpose of this study, the term 'small business' is used to indicate the small and medium sized enterprises (SMEs) or industries (SMIs) as defined by the Central Bank of Malaysia. Under this definition, SMEs or SMIs are those registered businesses with net assets of up to RM2.5 million or in the case of limited companies, with shareholders' funds of not more than RM2.5 million. Definition by the Central Bank is strictly observed in all commercial bank lending in Malaysia. The small business sector, therefore, refers to all businesses that fulfill the above definition. A great majority of these businesses are independently owned and operated by individuals and families.

WHAT IS RELATIONSHIP BANKING?

The acceptance and application of relationship banking have grown in the banking sector where an emphasis is being placed on the management of customer relationships (Barnes & Howlett, 1998; Dibb & Meadows, 2001). According to Moriarty, Kimball & Guy (1983), relationship banking is a recognition that a bank can increase its earnings by maximizing the profitability of the total customer relationship over time, rather than by seeking to extract the most profit from any one individual product or transaction. Because most banking customers purchase many products and services, and do so on recurring basis, the bank must build and maintain a number of product or service relationships to reach the full potential of the customer. Relationship banking emphasizes deeper penetration of the existing customer base. Main (1982) argues that in relationship banking, the customer gets to deal with a real human being, preferably one who is knowledgeable and courteous and who will get to know his name. What the customer seems to want more than anything else is a sense of importance, like being recognized by a head waiter. Levitt (1983) says that the relationship between a seller and a buyer seldom ends when a sale is made. Increasingly, the relationship intensifies after the sale and helps determine the buyer's choice the next time around. In banking, becoming the designated supplier requires successful passage through several consecutive gates or stages in the sales process.

Relationship banking can also be seen as the bank's relationship with the customer that is not confined to contact when a credit limit is exceeded, or a new application made for a loan, but which is renewed on a regular basis so that the banker builds up a real understanding of the firm's progress and financial needs (Read, 1998). The underlying principle behind relationship banking is that banks can enhance customer satisfaction and in so doing can enhance their own performance. For such benefits to accrue, relationships must be developed and managed to the customer's satisfaction.

BANK-SMALL BUSINESS RELATIONSHIPS

Past studies have documented the problematic relationships between banks and their small business customers. Wynant & Hatch (1990) argue that banks did not have sufficient knowledge or understanding of how small businesses operate and of what their needs are. Clay & Cowling (1996) reveal that lending decisions on small businesses were not based on actual prospects of the business but instead on the likelihood of the banks being collateralized and secured. Banks were seemed much more concerned with how a long would be repaid if the business failed rather than the prospects for success and greater involvement with the small business customers (Lambden & Targett, 1993). However, Wynant & Hatch (1990) assert that banks are in the business of providing low risk financing to small businesses, and sometimes, may find that the purposes sought by the small business owners are not necessarily appropriate for bank financing.

The significant cause of conflict in the bank-small business relationship is the asymmetry of information between the two parties, that is, the small business owner is generally more informed on the financial circumstances and prospects of the business than the bank (Storey, 1994). This situation can give rise to a twin problem of moral hazard and adverse selection. In the former situation, the issue arises where the action of a small business borrower is not directly observable by the banker once he obtains the loan. This borrower may use the borrowed funds for other purposes that may be detrimental to the bank. An adverse selection occurs because the banker cannot distinguish the good risk and the bad risk borrowers (Cowling & Sugden, 1995). A small business owner when approaching the bank for loan has always an advantage over the banker which leads him to overstate the soundness of the business in relation to the funding sought. This explains why some small business ventures, which have high potential for growth and profitability are sometimes turned away by the banks.

The concept of relationship banking has been advocated by some researchers as an effective strategy to overcome the problems in the bank-small business relationships (Madill, Feeney, Riding & Haines, 2002; Blackwell & Winters, 1997; Cole, 1998; Berger & Udell, 1995). It is argued that banks can gain information on their customers over the course of their relationships and then use this information to help in making lending decisions. Information may be gathered over time through a series of loans extended to the small borrower, and the provision and delivery of other financial services. Conditional on this experience, the bank may expect the loans to be less risky, and as a consequence, reduces the interest charged. The customer may not only benefit in terms of lower cost but also in greater access to bank funds due to efficient gathering of information (Berger & Udell, 1998).

Peterson & Rajan (1994) examined the relationship between a small firm and its creditors and how it affects the availability and cost of funds. They found that the length of relationship has a positive and significant effect on the availability of credit to small firms. Likewise, Blackwell & Winters (1997) found a positive relationship between a bank's monitoring effort and the interest rates. Banks would monitor less frequently customers with whom they have closer relationship and ultimately charge them lower interest rates. Bank is also more likely to extend credit or loan to a customer which it has a pre-existing relationship as a source of financial service (Cole, 1998).

The relevance of a borrower's credit in the relationship is also emphasized. The longer the borrower repays his loans, the more likely the business is considered viable, and his trustworthiness. This leads to a building of a good reputation, an increase in the availability of funds, and a relatively lower rate of interest charged on loans. On the other hand, borrowers who default in loan repayments may be denied credit thereafter. Consequently, this leads to an improvement in the quality of small borrowers, and the lowering of lending rates.

The benefits of a good relationship between banks and small business are considerable. From the bank's perspective, as it becomes more knowledgeable about the small business, it will improve its ability to retain the business. This include the potential profit of that business as the customer grows and positive promotion among the small business community. From the small business's perspective, if it can develop closer and stronger bonds with its bank, then it is more assured of financial support even in times of difficulty.

Given the importance of good bank-small business relationships, and given the problems experienced by the two parties, the issue in the Malaysian context is worth exploring further.

METHODOLOGY

The sampling method used in this study was a simple random sample. A total of 150 questionnaires were distributed to the small business owners in the northern region of peninsular Malaysia. However, achieving a representative sample of small business owners in Malaysia is problematic, since appropriate sampling frames do not exist. The questionnaires were handed personally to the owners either in the offices or business premises, and a significant number of questionnaires were left for subsequent completion. The respondents were then asked to return the questionnaire in the self-addressed enveloped provided. A total of 64 useable questionnaires were received, representing a 42.6 percent return rate.

The questionnaire consisted of two parts. The first part included the demographic characteristics of the respondents such as gender, age, years of business, number of employees and types of business ownership. The second part was related to the small business owners' interaction and relationship with the banks. The questionnaire had open questions, classification questions, preference questions and attitude questions. Because of the exploratory nature of the study and the nature of the sample, formal statistical tests were not used. The data analysis is based on frequency distributions and cross-tabulations. Some of the questions could be answered by 'yes' or 'no', and other questions respondents were asked to rate with various indicators, using a 3 point scale from '1' for a poor evaluation to '3' for a good response. Owing to the fact that, a large number of those who responded have 15 or less number of employees, the findings of this study will reflect the views of mainly the micro or smaller business segment of the small businesses in Malaysia.

FINDINGS AND DISCUSSION

CHARACTERISTICS

The profile of respondents and business characteristics are outlined in Table I below.

Table I

1.Gender	Frequency	Percentage
Male	40	62.5
Female	24	37.5
Total	64	100.0
2. Age (years)		
Below 30	9	14.1
30 – 40	20	31.3
41 – 50	22	34.4
Above 50	13	20.3
	64	100.0
3.Business ownership		
Sole proprietorship	33	51.6
Partnership	15	23.4
Limited companies	16	25.0
	64	100.0
4. Age of business (yrs)		
Less than 5	18	28.1
5 – 10	18	28.1
11 – 15	13	20.3
16 –20	9	14.1
More than 20	6	9.4
	64	100.0
5. No. of employees		
Less than 5	42	65.6
5 – 10	15	23.4
11 – 15	4	6.3
More than 15	3	4.7
	64	100.0

Most of the respondents ranged in age from above 40 years with 54.7 percent, between 30 to 40 years with 31.2 percent and below 30 years with 14.1 percent. This shows that the small business owners in this study were of middle age group. In terms of gender, only 37.5 percent of the respondents were female. All the three types of business ownership were represented with the largest number of respondents came from sole-proprietorship (51.6 %), followed by limited companies (25.0 %) and partnership (23.4 %). 65.6 percent of the respondents reported an employee level of less than 5, another 23.4 percent had an employee level of between 5 and 10, and only 4.7 percent had more than 15 employees. About 28.1 percent of the respondents had been in business for less than 5 years, another 48.4 percent ranged from 5 to 15 years, and only 23.5 percent had been running the business for more than 15 years.

SATISFACTION IN BANKING RELATIONSHIP

The respondents were asked to rate their levels of satisfaction on the overall relationship with the banks, the relationships with the bank personnel and the quality of services provided by the banks. Table II below shows that the majority of respondents (70.3%) rated 'good' and above in their overall relationship with the bank. 17.2 of them gave a 'very good' rating. Only 2 respondents or 3.1 percent felt that their banking relationship was poor. However, none gave a 'very poor' rating. On their relationship with the bank personnel, the respondents gave an even higher rating of 'good' and above (73.4%), and only 1.6 percent with a 'poor' rating. The unexpectedly high ratings given by the small business owners to the overall banking relationship contrasted those found in most literature where small business owners, generally, had problematic relationships with their bank.

Table II: Relationship with the Bank

Levels of satisfaction	Frequency	Percentage
Very good	11	17.2
Good	34	53.1
Average	17	26.6
Poor	2	3.1
Very poor	0	0
	64	100.0

Table III: Relationship with the Bank Personnel

Levels of satisfaction	Frequency	Percentage
Very good	8	12.5
Good	39	60.9
Average	16	25.0
Poor	1	1.6
Very poor	0	0
	64	100.0

Respondents were also asked how they would rate the overall quality of service which they receive from their bank. Table IV below shows 12.5 percent of the respondents replied 'very good', 53.1 percent gave 'good' rating and only 6.3 percent believed the quality of service to be poor.

Table IV: Quality of Services provided by Bank

Levels of satisfaction	Frequency	Percentage
Very good	8	12.5
Good	34	53.1
Average	18	28.1
Poor	4	6.3
Very poor	0	0
	64	100.0

IMPORTANT ELEMENTS IN THE BANKING RELATIONSHIP

The respondents were also asked to rate the importance of ten factors in relation to a good banking relationship. The results presented in Table V below show that there was a strong agreement among the respondents with regard to the importance of cost factor and elements of bank service of the banking relationship. Over 68 percent of respondents rated the factor 'bank offers best terms and rates, 64.1 percent rated 'bank handles credit request quickly' and another 59.4 percent of respondents rated 'bank offers a wide range of services' as being 'very important' for a good banking relationship. Surprisingly, a significant percentage of respondents believe that the interpersonal elements of the banking relationship were not of being importance. "Bank manager treats me with respect' (17.2%), 'bank manager makes me feel comfortable'(14.1%), 'bank manager is easy to talk to' (12.5%), and 'bank has specialized personnel'(10.9%) were some of the factors rated as 'not importance'.

Table V

Factor	VI	%	I	%	NI	%
1. Bank knows me and my business	36	56.3	25	39.1	3	4.7
2. Bank provides helpful business advice	32	50.0	27	42.2	5	7.8
3. Bank offers best terms and rates	44	68.8	19	29.7	1	1.6
4. Bank offers a wide range of service	38	59.4	24	37.5	2	3.1
5. Bank handles credit request quickly	41	64.1	21	32.8	2	3.1
6. Banker is easily accessible	34	53.1	29	45.3	1	1.6
7. Bank has specialized personnel	23	35.9	34	53.1	7	10.9
8. Bank manager is easy to talk to	29	45.3	27	42.2	8	12.5
9. Bank manager makes me feel comfortable	27	42.2	28	43.8	9	14.1
10. Bank manager treats me with respect	26	40.6	27	42.2	11	17.2

VI – Very important   I – Important   NI – Not important

The respondents were then asked to rate their bank's performance on the same ten factors of good banking relationship. Table VI below shows that 'bank offers a wide range of service', 'bank knows me and my business', 'banker is easily accessible', 'bank handles credit request quickly' and 'bank offers best terms and rates' had more than 50 percent of 'good' rating. On the other hand, only 'bank provides helpful business advise', 'bank has specialized personnel' and 'bank manager is easy to talk to' are found to have more than 10 percent 'unsatisfactory' rating.

Table VI

No.	Factor	GD	%	AC	%	UN	%
1.	Bank knows me and my business	37	57.8	25	39.1	2	3.1
2.	Bank provides helpful business advice	29	45.3	24	37.5	11	17.2
3.	Bank offers best terms and rates	33	51.6	28	43.8	3	4.7
4.	Bank offers a wide range of service	41	64.1	22	34.4	1	1.6
5.	Bank handles credit request quickly	35	54.7	26	40.6	3	4.7
6.	Banker is easily accessible	36	56.2	25	39.1	3	4.7
7.	Bank has specialized personnel	22	34.4	34	53.1	8	12.5
8.	Bank manager is easy to talk to	30	46.9	27	42.2	7	10.9
9.	Bank manager makes me feel comfortable	32	50.0	27	42.2	5	7.8
10.	Bank manager treats me with respect	34	53.2	25	39.1	5	7.8

GD – Good, AC – Acceptable, UN - Unsatisfactory

Table VII below analyses the respondent's satisfaction with the banking relationship in terms of 'scores' awarded to each factor by each respondent. The banks are found to score well on 'wide range of service', followed by 'knows me and my business', and 'easily accessible'. However, the banks performed less well on 'specialized personnel' and 'helpful business advice'.

Table VII: Bank Performance Scores

Factor	Total	Average
1. Bank knows me and my business	35	0.54
2. Bank provides helpful business advice	18	0.28
3. Bank offers best terms and rates	30	0.46
4. Bank offers a wide range of service	40	0.62
5. Bank handles credit request quickly	32	0.50
6. Banker is easily accessible	33	0.51
7. Bank has specialized personnel	14	0.21
8. Bank manager is easy to talk to	23	0.35
9. Bank manager makes me feel comfortable	27	0.42
10. Bank manager treats me with respect	29	0.45

PROBLEMS IN THE BANKING RELATIONSHIP

The respondents were also asked on the problems they encountered in their banking relationship. Table VIII below shows that the most frequently cited bank related problems were the slow and poor counter service, unhelpful attitude of bank staff, difficulties in getting access to bank loans, high charges for loans and advances, and no 24 hours or ATM services.

Table VIII

	Problem	Frequencies	Percentage
1.	Slow and poor counter service	29	45.30
2.	Unhelpful attitude	16	25.00
3.	Difficulty in obtaining loan	12	18.75
4.	High interest charges	7	10.93
5.	No 24 hours or ATM service	7	10.93

Slow and poor counter service was a major source of problem in the banking relationship, and was mentioned by 45 percent of the respondents. The main complain were that there were often long queues at the counters, insufficient staff to handle the customers, and the longer time taken to handle cases. The second main problem cited was the perceived unhelpful and unfriendly attitudes shown by the bank staff. The complaints were that of staff complacency and arrogance when dealing with customers. These bank staffs were not seemed to be interested in giving customer satisfaction. There was also a feeling among some of the respondents that bankers did not understand them, the needs and the problems of their business. These bankers did not show their interest when approached for loans. Thus, they faced difficulties in getting access to bank loans. Some of the respondents who obtained advances and loans felt that the charges were too high and the terms and conditions imposed on them were unfavourable. The problem cited on the availability of 24 hour and ATM service shows that some small business owners seem to prefer dealing with their bank through Automatic Teller Machines. Therefore to attract more small business customers, banks must provide as many services as possible through the ATMs.

CONCLUSION

The study was conducted to generate an understanding of the nature of bank and small business customer relationships in Malaysia. The findings reveal that there was a relatively high level of satisfaction among small business customers with regard to their bank. The small business customers gave very high 'good and above' ratings on their relationships with the bank, relationships with the bank personnel and quality of services provided by the bank. This shows that, generally, small business customers in Malaysia have high regards in their relationship with the bank. This is in contrast to a number of literature which suggest that most small business owners have a problematical banking relationship.

The findings also reveal that there was a strong agreement among the small business owners on the importance of price competitiveness and speed of bank decisions in the banking relationship. Nevertheless, these two factors were only given marginally high ratings on the performance by their banks. The banks also performed less well on 'specialized personnel' and 'helpful business advise'. These findings should be helpful for the banks to understand further what the customers are looking for and how they evaluate the quality of service. Some issues of concern are highlighted that may make small business customers feel aggrieved with their bank. Poor counter service, unhelpful attitude of bank staff and difficulties in getting access to bank loans are some of the problems encountered by the small business customers in dealing with the bank. Bank should therefore place more emphasis on personnel training so that they can be accurate in tending to the customer needs, quickly response to small business customers, being knowledgeable and appreciative of the small business customer needs.

The ability to develop strong relationships with small business customers has become increasingly important in today's banking environment, and understanding the very real concerns shared by most of these customers will provide a head start in the process of moving towards effective management in the banking relationship. Nevertheless, the findings of this study should be viewed with caution because of the limited generalisability of studies involving small business owners. The study was focused mainly in the northern region of Peninsular Malaysia and the findings may be less valid in some other regions. This should be kept in mind when reviewing the results and may be a direction for future research.

Capital Structure Choices in Listed Malaysian Firms:
A Recent Relook

ABSTRACT

This study empirically examines the relationship between capital structure and its traditional determinants (like tangibility, growth opportunities, size, beta) and new determinants like foreign shareholdings and CEO ethnicity. Using data for 205 Malaysian listed Main Board firms for 2001 and 2002, the study concludes that debt financing decision is typically supported by collateral and preferred by big and more risky companies. High growth opportunities and dividend payout firms typically use less debt. More interestingly, Malaysian managers typically shy away from using debt as a means of bonding them to increase efficiency and to discourage themselves from engaging in negative net present value projects. Foreign shareholders though could act as blockholders, are not monitoring the management. However, the finding is only weakly significant. That same conclusion however cannot be extended to companies that are managed by foreign CEOs who tend to prefer more debt in their capital structure. Locally managed companies do not exhibit any conclusive preference for debt although the Chinese CEOs prefer more debt than the Bumiputera CEOs.

INTRODUCTION

Modigliani and Miller (1958) initiated studies in capital structure with their capital structure irrelevance theory. Subsequently, alternative capital structure theories like trade-off theory, pecking order/asymmetric information theory and the agency theory followed. In the developed countries, these theories have been subjected to extensive research in the United States in particular. There have been several studies that examine international comparisons of capital structure determinants (Rajan and Zingales (1995); Wald (1999). However, in developing countries of South-east Asia, there have been few empirical studies on capital structure Pandey, 2001; Ahmad-Zaluki, Abdullah, Abidin, Ali, and Arshad, 2001; Taridi, 1999; Wiwattanakantang, 1999; Setiawan and Taib, 2002; Setiawan, 2004.

The objective of this paper is to investigate whether previous determinants of capital structure still persist and at the same time try to identify whether the ethnicity of the Chief Executive Officer (or Managing Director or Executive Chairman) that is person who makes financing decisions would influence the choice of capital structure in Malaysia. Furthermore, the use of the latest data set covering 2001 and 2002 would provide the latest evidence of capital structure choice especially when the Asian Financial Crisis has already settled.

The remaining sections of the paper are organized as follows: Section two presents a model development on capital structure before a model is proposed. The next section describes the data and research methodology. Section four reports the results of the statistical analyses while section five summarizes the main conclusions of the study.

MODEL DEVELOPMENT

The agency theory supports the use of debt as a means of curbing agency problems and subsequently the reduction of agency costs. Jensen and Meckling (1976) propound that conflicts between shareholders and debtholders results in the occurrence of risk shifting which tends to favour shareholders when risky investments are undertaken (asset substitution). In case, the investment result in profit, the shareholders stand to gain but on the contrary should the investment fail, the debtholders suffer losses. Another finance theory that supports the use of high debt is the tax-shield theory (Modigliani and Miller, 1963). This theory states that profitable firms tend to favour borrowings in order to save taxes as interest charges are tax deductible. Hence, agency theory and tax-shield theories support the use of high debt and predict a positive relationship.

However, if the benefits obtained by debtholders result in a reduction of shareholders returns, shareholders are inclined to reject positive net present value investments. Myers (1977) postulates that to curb this under-investment problem, companies with growth opportunities should not resort to debt financing.

Many variables have been found to be determinants of capital structure. For example, in an international study, Rajan and Zingales (1995) find profitability, size, growth and tangibility (fixed assets divided by total assets) to be significant determinants of capital structure. Other studies have shown that risk and investment opportunities are also important determinants of capital structure for example, Titman and Wessels, 1998; Pandey, Chotigeat, and Ranjit, 2000; Pandey, 2001; Tay, 2001.

The trade-off theory states that tangible assets serve as collateral for borrowing and gives security to lenders in case of financial distress. Jensen and Meckling (1976) argues that collateral help reduce moral hazard problems in shareholder-debtholder conflicts. This suggests that firms that have more tangible assets can be expected to take on more debt. Empirical studies that find a significant positive relationship between asset tangibility and debt are Titman and Wessels, 1988 and Rajan and Zingales, 1995 but Wiwattanakantang, 1999 and Pandey, 2001 find a negative relationship.

Myers (1977) put forth the idea of underinvestment and attributed the problem to shareholder-bondholder conflict. The underinvestment problem arises when firms with investment/growth opportunities but have an overhang of debt which prevents the firm from investing in those valuable projects. Investment opportunities refer to a firm's "assets not yet in place" or its intangible value and because of its nature, there is no collateral. The intangible value will disappear when there is financial distress. Myers (1977) argues that high growth firms may not issue debt as it effectively transfers wealth from shareholders to debtholders. Hence, firms with high growth opportunities (for example, high technology firms) may not issue debt to reduce the agency costs of debt. Myers (1977) posit that firms with high investment/growth opportunities use less long-term debt to reduce moral hazard that is agency problem of underinvestment. Myers (1977) argues that the agency problem may be reduced for short-term debt in contrast to long-term debt that is "shortening debt maturity". The agency theory predict that leverage is negatively related to investment/growth opportunities.

Wealth transfer is another major source of bondholder-shareholder conflict. Smith and Warner (1979) suggested that dividend payment to shareholders is one form of wealth transfer. This is because dividend payout involves the transfer of cash from the firm to the shareholders and as a result, debtholders have less cash available for settling their debt. The other alternative is by issuing debt with the same or higher priority which is not examined in this study due to the lack of data. This study seeks to test whether the wealth transfer problem (via dividends) exist in Malaysia. From the limited literature on wealth transfer, it is interpreted that high dividend payout reflects the presence of wealth transfer. In this case, there will be a positive relation between dividend payout and leverage. If there is a negative relation between dividend payout and leverage, it shows that there is no wealth transfer problems exist. This is due to arguments that suggest that dividend payments and debt act as substitutes in reducing agency costs of debt (Moh'd, Perry and Rimbey, 1998). Empirical findings have so far find a negative relationship between dividend payout and leverage like Jensen, Solberg and Zorn, 1992; Tho, 1994.

Overinvestment is a situation in which managers reinvest excess cash flows in projects with negative net present values. Jensen's (1986) free cash flow hypothesis suggests two conditions (free cash flow or profit and few growth opportunities) in which a firm should have higher debt (or self-imposed debt) to mitigate the overinvestment problem. Unlike the case of Myers' (1977) underinvestment problem which is applicable to firms with growth opportunities, Jensen's overinvestment problem mainly applies to firms with lack of growth opportunities. By increasing debt, managers bond themselves to make regular payments to debtholders and discourage firms from wasting its cash resources in value decreasing investments. This is because debt forces the firm to commit itself to regular cash payments and this reduces the free cash flow available to managers for them to reduce their scope for self-interest activities. Firms with high profit or high cash have a tendency to increase its size ("empire building") even though it results in negative net present value projects. In addition, Grossman and Hart (1982) supports the use of debt finance because it "pressures" managers to increase efficiency and make better investment decisions. The evidence of overinvestment is when there is a positive relationship between free cash flow and leverage. Pandey (2002) use profitability as a proxy for free cash flow.

Size is another important determinant of capital structure. Being more diversified and hence, lower probability of bankruptcy, large firms can be expected to accommodate more debt. However, the empirical evidence is not

conclusive. Studies that detect a positive relationship between debt ratio and size include Rajan and Zingales, 1995; Wiwattanakantang, 1999; Pandey, et al. 2000; Tay, 2001; and Ahmad-Zaluki, et al. 2002. Other studies like Kester (1986) and Johnson and Mitton (2003) find no significant relationship between debt ratio and firm size.

Foreign investors can be regarded as blockholders and they have an incentive to monitor and influence management to protect their significant investments (Mehran, 1992). Shleifer and Vishny (1986) suggest that blockholders (in this case, foreign shareholdings) can reduce the opportunities for managerial opportunism and reduce manager-shareholder conflicts. Foreign or blockholders can act as a substitute for the role of debt to monitor management and reduce agency costs of equity. According to Ferris, Kumar and Sarin (1995, p.324), "blockholders have claims on a large fraction of the firm's cash flows, making it cost effective for them to engage in expensive monitoring of the firm". Usually foreign investors may contribute more to disciplining management by demanding for more information than local investors (Suto, 2001). Hence, if the relationship between foreign investors and debt-equity ratio is positive this would imply that foreign ownership (a control devise) is used as a substitute for debt. On the contrary, if the relationship between foreign investors and debt-equity ratio is negative, this implies that foreign investors do not monitor management. Pound (1988) argue that large shareholders may not be active monitors but instead, they may be passive voters who collude with management.

Haniffa and Cooke (2002) examined the link between Chief Executive Officer (CEO) ethnicity and corporate disclosure. This study seeks to establish a link between CEO ethnicity and capital structure. For Malaysia, the effect of CEO ethnicity is unique because it is a multi-cultural nation and CEOs of local listed firms have come from various ethnicities like Bumiputera, Chinese, Indians and others (foreigners). As a result of their relatively inexperience Bumiputera CEOs may be generally more risk averse than the Chinese or Indian CEOs. Hence, it is possible that Bumiputera CEOs have a tendency to make investment decisions using low debt. If this is the case, there will be a negative relation between Bumiputera CEO and leverage. However, it can be also argued that Bumiputeras being politically more powerful and with their strong political connections are able to get access to more debt from the financial institutions. Hence, in this case, Bumiputera ownership will be positive. The Chinese and the Indian CEOs being longer in business tend to have a longer track record, generally tend to prefer higher risk and as a result may tend to have more debt. In addition, Foreign CEOs (that is non-Malaysian CEOs) may have tendency to use debt as a control debt. As a result of their head office being far away, debt may be used as a control device to keep any deviant actions of their managers in check. Hence, if this is the case, we would expect foreign firms to use more debt. On balance, it is expected that CEO ethnicity has an effect on leverage.

DATA AND METHODOLOGY

In this study, data on all firms listed on Bursa Malaysia (previously Kuala Lumpur Stock Exchange) for the period from 2001 and 2002 were used. Firms in the Finance sector in Malaysia (that is banks, insurance and stock broking firms) are excluded in this study because government regulations imposed on banks, finance companies and stock broking firms result in their capital structure being different and hence non-comparable with non-financial firms. Likewise, many other Asian studies (including Malaysian) on capital structure also exclude non-financial firms are Fan and So (1999), Isa and Kam (2001), and Pandey (2002). Among the other selection criteria for the sample firms are zero sales and negative shareholders' equity. Companies that change their financial year have also been included but their data is annualized. In case, the financial year of samples extend more than 12 months, the data is first annualize the following year data and the substitute the missing data with the mean value.

Model

Briefly, the dependent variable (DE) is the debt-equity ratio and the independent variables consist of eight dimensions of ownership variables, four dimensions of agency costs variables and three control variables. Multiple regression or panel data may be used to test the model.

The multiple regression equation model for this study is as follows:

$$DE_{it} = \alpha_0 + \beta_1 TANG_{it} + \beta_2 Q_{it} + \beta_3 DIV_{it} + \beta_4 FCF_{it} + \beta_5 SIZE_{it} + \beta_6 BETA_{it} + \beta_7 FOREIGN_{it} + \beta_8 CH_{it}$$
$$+ \beta_9 F_{it} + \beta_{10} B_{it} + \varepsilon_{it}$$

Total debt-to-asset ratio (DE) at book value is the dependent variable. Independent variables include tangibility of assets (TANG), growth opportunities (Q), net dividends paid (DIV), firm size (SIZE), unsystematic risk (BETA),

foreign shareholdings (FOREIGN), Chinese Managing Director/Executive Chairman (CH), Foreign Managing Director/Executive Chairman (F) and Bumiputera Managing Director/Executive Chairman.

Total debt-to-asset ratio (DE) is measured by total debts divided by book value of total assets. Tangibility of assets is measured by gross fixed assets minus depreciation and amortization divided by total assets. Tobin's Q (Q) is approximated by as the sum of market value of ordinary shares/equity and book value of long-term debt and net current assets (current assets minus current liabilities) divided by the book value of total assets. This approximation of Q has been used by Chung and Pruitt (1994) owing to the unavailability of replacement costs for fixed assets in Malaysia. Dividends (DIV) is measured by the net amount of dividends paid scaled by total assets. Size (SIZE) is measured as the natural log of total assets. Risk (BETA) is defined as unsystematic risk and is measured by unlevered beta. Beta for each firm is calculated using the adjusted (to take into account capitalization changes) weekly share price data. Foreign shareholdings (FOREIGN) is measured as the percentage of foreign shareholdings divided by total shareholdings.

RESULTS

Table 1 provides the means and standard deviations of the dependent and independent variables. The average total debt ratio (DE) for the period 2001-2002 is 23% and is lower than Pandey (2002) study for 1994-2000. Foreign shareholdings range from 1% to 64% for the sample firms. Data for growth opportunities [Q], Dividend [DIV] and free cash flow [FCD] were standardized to meet the normality assumption. Other than the three variables mentioned, the rest of the data do exhibit the necessary distribution.

Table 1: Descriptive Statistics

	DEBT	TANG	Q	DIV	FCF	SIZE	BETA	FOREIGN
Minimum	0.000	0.001	-3.103	-0.659	-6.216	9.831	-0.544	0.960

Observations	410	410	410	410	410	410	410	410

Table 2 provides the correlation matrix for the pooled sample firms. We find that size, tangibility and beta have a significant positive relationship with total debt while growth opportunities, dividend, free cash flow and foreign shareholdings have a significant negative relationship. The extent of correlation among the variables is acceptable with no particular variables exhibiting potential for multicollinearity.

Table 2: Correlation Matrix

	DEBT	TANG	Q	DIV	FCF	SIZE	BETA	FOREIGN
DEBT	1							
TANG	.110**	1						
Q	-.401***	-.019	1

FOREIGN	-.190***	.037	.215***	.300***	.040	.096	-.152***	1

Note:*** denotes significance at less than 1% level
        ** denotes significance at less than 5% level

The model was run as specified but the variance inflation factors (VIF) shows extremely high values for the two dummies, CH and M with a value between 22-24. As a result, it is decided that the model be repeated with an

inclusion of each dummy separately. The results of the regression are displayed in Panel A (for CH dummy) and in Panel B (for M dummy) in Table 3.

$$DE_{it} = \alpha_0 + \beta_1 TANG_{it} + \beta_2 Q_{it} + \beta_3 DIV_{it} + \beta_4 FCF_{it} + \beta_5 SIZE_{it} + \beta_6 BETA_{it} + \beta_7 FOREIGN_{it} + \beta_8 Ch_{it} + \beta_9 F_{it} + \beta_{10} Bit + \varepsilon_{it}$$

Total debt-to-asset ratio (DE) is measured by total debts divided by book value of total assets. Tangibility of assets [TANG] is measured by gross fixed assets minus depreciation and amortization divided by total assets. Growth opportunities -Tobin's Q (Q) is approximated by as the sum of market value of ordinary shares/equity and book value of long-term debt and net current assets (current assets minus current liabilities) divided by the book value of total assets. SIZE is measured as the natural log of total assets. Risk is defined as unsystematic risk and is measured by unlevered beta. Beta [BETA] for each firm is calculated using the adjusted (to take into account capitalization changes) weekly share price data. DIV is defined as dividend paid over total fixed assets while FCF is measured by operating profit before taxes plus depreciation and amortisation minus taxes and dividends paid. Foreign shareholdings [FOREIGN] is measured as the percentage of foreign shareholdings divided by total shareholdings. The remaining three variables - CH, F and B are dummy variables that take a value of 1 if they are Chinese [CH], Foreign [F] or Bumiputera [B] Managing Director/Executive Chairman respectively.

The results for both models are very similar. In Malaysia, the finding for TANG suggests that there is no moral hazard problem in the form of giving out loan without collateral. Companies that have secured loans have sufficient collateral to back their borrowings. Similarly, high growth opportunities companies use less debt to finance their growth. This finding is also in line with the previous studies findings for example, Titman and Wessels, 1988; Lasfer, 1995; Rajan and Zingales, 1995; Pandey, 2002. Similar conclusion emerges from companies with high dividend payout, as they tend to use less debt.

With regard to free cash flow hypothesis as posited by Jensen (1986), a positive relationship is observed if managers choose to get more debts to avoid engaging themselves in projects with negative net present values. However, results from Table 3 seem to suggest otherwise. Managers of Malaysian companies tend to use less debt when they have enough free cash flow in hand although this finding is only weakly significant at less than 10% level. It is not that evident from this finding whether their reluctance to get more debts as monitoring mechanisms is an indication

of engagement in negative net present values projects. It is however, interesting to observe that Malaysian managers are conservative in getting more debts and less proactive in committing themselves to the additional pressure to increase efficiency. Findings by Ahmad-Zaluki et al. (2002) did not find a significant relationship between free cash flow and debt ratio.

SIZE and BETA results follow that of the normal story of being big more access to loan is granted. Another interesting observation that emerges from this study is that the contradictory finding to the preference for debt by foreign investors. As postulated earlier, foreign shareholders are expected to have extra incentives to monitor and influence management in order to protect their significant investment abroad. Results suggest otherwise. Companies that are owned by foreign shareholders typically would shy away from getting on more debts although this is only weakly supported. The finding implies that foreign investors do not monitor management.

With regard to CEO ethnicity, companies that are headed by foreign CEOs apparently would prefer debt as to increase efficiency or ready to be subjected to pressures of using more debt. This finding is statistically significant at less than 5% level. For Chinese (CH) and Bumiputera (M) CEOs although the signs of the coefficient are in the predicted directions, they are not significant; suggesting that they do not have particularly have strong preference for their choice of capital structure.

CONCLUSION

This study empirically examines the relationship between capital structure and its traditional determinants (like tangibility, growth opportunities, size, beta) and new determinants like foreign shareholdings and CEO ethnicity to see their influence on capital structure decisions. Using data for 205 Malaysian listed Main Board firms over a period between 2001 and 2002, the study concludes that debt financing decision is typically supported by collateral and preferred by big and more risky companies. High growth opportunities and dividend payout companies typically use less debt. More interesting observations is made when Malaysian managers typically shy away from using debt as a means of bonding them to increase efficiency and to discourage in engaging themselves in negative net present value projects.

It is equally interesting to note that foreign shareholders though could act as blockholders, are not monitoring the management. However, the finding is only weakly significant. That same conclusion however cannot be extended to companies that are managed by foreign CEOs. These companies tend to prefer more debt in their capital structure probably to be more proactive in meeting the pressures of having to make regular cash payments and limit deviant activities. The locally managed companies do not exhibit any conclusive preference for capital structure although the Chinese CEOs prefer more debt than the Bumiputera CEOs.

The findings reported in this study are necessarily tentative as the data coverage is only over two year period. Nonetheless, it does give some clear pictures the kind of agency problems that Malaysian companies might encounter especially after the full exercise of corporate governance improvements in the post Asian Financial Crisis era.

International Business Operators' Decision Criteria in Selecting Banks

Marlin Marissa Malek Bt. Abdul Malek and Abd Rahim B. Jaguli

ABSTRACT

Bank selection is not an easy task especially when you are running a business in the era of globalization. A lot of marketing research in the past 10 to 15 years has attempted to identify the banking needs of both small and large business customers. Schlesinger, Unsal and Zaman (1987) found that the three most important factors in selecting a bank were lending rates, accessibility of borrowing and the number of services offered. The research aimed to identify the main criteria international business operators look for in selecting banks. In this context, international business operators were only limited to forwarding and shipping agents in Klang Port, Selangor, Malaysia. Questionnaire surveys and interview sessions were undertaken to collect data from the forwarding and shipping agents listed in the E-Directory of the Federation of Malaysian Manufacturers (FMM). The respondents were also asked to rank the criteria that they thought was the most important in selecting banks. Data then were analyzed using Descriptive Statistical Analysis. Findings indicated that the most important criterion that international business operators look for in selecting banks was safety of funds and confidence. The least important criterion was effective advertising. Hopefully, this research could help the banking organizations to provide better banking services to the respondents in the future.

INTRODUCTION

The banking environment is changing more rapidly than before. It is characterized by intensifying competition from both domestic and foreign companies, a spate of mergers and acquisitions and more sophisticated and demanding customers who have greater expectations related to their experiences (Smith, 1989). Consequently, banks today must differentiate their organizations by meeting the needs of their customers better than the competition. Rapid environmental changes will necessitate continued attention and emphasis in formulating bank marketing strategies on the part of management.

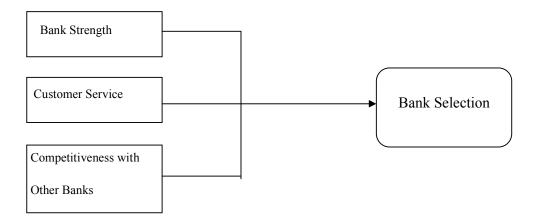
In its true sense, bank marketing involves a commitment on the part of management to adopt a consumer-oriented approach as their philosophy of doing business (Ta, H.P., Har, K.Y., 2000). Eli Lenyoun, vice-president of financial planning at the United Overseas Bank (UOB) Singapore commented that an essential first step in bank marketing is to ensure that its services correspond with a client's short and long term needs. He also stressed the importance of developing an early banking relationship with a client because "bankers are looking for opportunities to have relationships with people who are going to develop. They want to be there when you develop because the more banking services you use, the more profitable the relationship with that particular customer" (*Asia Magazine*, 1996).

Regardless whether they are individual or corporate customers, bank customers nowadays are more 'picky' in choosing financial or banking service providers. In addition, bank customers are more concerned with other factors like the environment of the establishment, satisfaction, reliability of bank personnel and the 'feel good' factor that makes them stay loyal to a certain bank or several banks; regardless whether it is foreign-originated or local banks. The fact of the matter is, banks need to determine what are the factors deemed important to their customers in order to be more competitive. Only then, might it be possible for them to tailor-made their banking services to all their business or corporate customers. Thus, this study aimed to identify the criteria international business operators look for in deciding which banks to patronize. Hopefully, the findings from this study could shed some light on the criteria that should be present in a bank to entice international business operators to choose that particular bank as their first preference.

PROBLEM STATEMENT

Providing banking services to business clients is no easy task. Business customers want to have banks that they can rely on because constant delays in banking procedures and other 'red-tapes' will eventually disrupt the

smooth operations of their daily activities. This research focused on international business operators or sometimes referred to as logistics service providers (LSPs) who normally does all the logistics related activities such as transportation of goods, provision of warehouse facilities, inventory management, order processing management and packaging. Due to the nature of the industry that involves cross-border activities, these international business operators need to rely on banking institutions for invoicing, freight bill payments, factoring, audit and insurance services. Naturally, they want the chosen banking institutions to provide them with relevant and efficient banking services to avoid glitches in their daily operations.

RESEARCH QUESTIONS


This study attempted to answer the following research questions:
- What are the main criteria international business operators look for in selecting banks?
- Which dimension of a bank deemed most important to international business operators?
- Which is the most preferred bank used by international business operators?

THEORETICAL FRAMEWORK

In the following theoretical framework, the dependent variable is bank selection while the independent variables are bank strength, customer service and competitiveness with other banks. A positive relationship can be expected between the three independent variables and bank selection. According to a study by Edris *et al*. (1997), there was indeed positive relationships between size of banks assets (bank strength), efficiency of personnel (customer service) and fees / interest on loans (competitiveness with other banks).

Figure 1: Theoretical Framework

Pilot Study

Before the actual distribution of questionnaires, a pilot study was conducted with the selection of five respondents who are international business operators in Klang Port. This was to establish reliability and validity of the questionnaires and was pertinent to further improve the questionnaires and avoid any confusion on the part of respondents before the actual distribution took place. In addition, this pilot study was relevant so that the feedback given by the respondents was reliable for the research. The responses from the pilot study were then collected and analyzed and the results from the reliability testing is illustrated below:

Table 1: Reliability Testing

DIMENSION	CRONBACH ALPHA
1.Bank strength	0.740
2.Customer service	0.779
3.Products and services offered	0.325
4.Competitiveness with other banks	0.671

Based on Table 1, three dimensions (1, 2 and 4) recorded an Alpha of more than 0.60, which indicated that these dimensions were accepted for further analysis. The third dimension, products and services offered had an Alpha of less than 0.60, which indicated that the items under this dimension do not really measure what it should be measuring and thus was omitted.

LITERATURE REVIEW

This industry has changed since the mid-1980s in the form of increasing competition in the marketplace, growing financial awareness by customers, economic pressures on traditional markets and government legislation. These changes have contributed in making the market for retail financial services more open (Davis, 1994). Birch (1995) warns that "Fierce competition will lead to fewer financial service organizations ... smaller banks will merge with larger ones, and many may disappear altogether". Ellwood (1994) suggests that: in the year 2000, the customer will see a banking marketplace where the blurring of identity between banks, insurance companies, and of other possible competitors that will enter in the market, will have accelerated... Customers will shop around more than ever and profitability will come under pressure. The result of this "shopping around" culture will be a higher mobility among customers buying financial products. Differentiation will continue to lead the marketing strategy of banks, but it will be centered neither on products, as they are about the same, nor on price, as price differentials are minimal. Therefore, how will a financial institution, such as a retail bank, compete in such an environment? How will it differentiate its offerings from those of its competitors (Birch, 1995; BMA, 1991)?

Financial institutions are acknowledging that unless customer needs are taken into account in designing and delivering services, technical superiority will not bring success (Zeithaml and Bitner, 1996). New marketing concepts and strategies (Ennew *et al*., 1993) are paying greater attention to identifying customer needs and expectations (Morgan, 1989) and offering high levels of service quality (Lewis, 1991; 1993; Thwaites and Vere, 1995). As argued in the literature (Brown and Swartz, 1989; Buzzel and Gale, 1987; Edvardsson *et al*., 1994; Grönroos, 1990; Lewis, 1989; 1991; Lewis *et al*., 1994; Parasuraman *et al*., 1988; 1991; Zeithaml and Bitner, 1996; Zeithaml *et al*., 1990), it is probably the effective measurement, management and improvement of service quality which will enable financial institutions to achieve a differential advantage over their competitors (Lewis, 1989; 1991).

The literature of bank marketing shows that little attention has been paid by researchers to business customers (sometimes called corporate customers). One early study was undertaken by Kaufman (1967) to determine the important criteria judged by retail and corporate customers influencing their selection and patronization of specific banks. The study found that the majority of the sampled respondents selecting the most convenient bank to their home, place of business, or both. Other few studies were conducted among corporate customers in Hong Kong to explore their banking behaviour and bank selection decisions (Chan and Ma, 1987, 1990; Kong and So, 1981). One study by Edris (1997) highlighted the determinant factors a bank in Kuwait by business firms. The ranking were size of bank assets (1), efficiency of personnel (2), help in financial emergencies (3), banking experience (4), friendliness of staff (5), reputation (6), communications with staff (7), knowledge of firm's business (8), prompt provision of services (9), and availability of branches abroad (10). The lowest-ranking determinant factors, on the other hand, were: effective advertising (27), interests on deposits (26), lending policy (25), Islamic banking practices (24), attractiveness of branches (23), parking areas and facilities (22), hours of operation (21), Kuwaiti ownership (20), fees/interest charges on loans (19), and convenience of location (18).

METHODOLGY

In general, this research attempts to determine the main criteria international business operators look for when deciding which banks to patronize. The research was conducted closely in accordance to similar researches in bank selection put forth by Edris, T.A. (1997), Nielsen,Terry and Trayler (1998) and Haron,Ahmad and Planisek (1994). The research was conducted using survey approach that consisted of multiple-choice questionnaires requiring respondents to give fixed responses to the statements or questions asked. The sources of the research

data were a combination of both primary and secondary data. The primary data for this research were gathered through the distribution of questionnaires to selected international business operators; namely logistics service providers, forwarding agents and other operators of the same nature in Klang Port, Selangor, Malaysia. The list of international business operators located in Klang Port, Selangor was obtained from the Federation of Malaysian Manufacturers (FMM) e-directory. A questionnaire was replicated from the earlier researches done by Edris, T.A. (1997), Nielsen,Terry and Trayler (1998) and Haron, Ahmad and Planisek (1994).

The population for determining the main criteria for bank selection among international business operators was every international business operators in the vicinity of Klang Port, Selangor, Malaysia. Due to time and resource constraints, nonprobability sampling method, more specifically, convenience sampling was applied for this research. The researcher conducted convenience sampling method by randomly selecting international business operators listed in the e-directory of international business operators. According to Sekaran (2000), if the population of a study is about 270, the sample is equivalent to 159. However, in this study, the researcher has distributed 170 questionnaires to international business operators located in Port Klang, Selangor listed in the Malaysian Manufacturers e-directory. Out of the 170 questionnaires distributed, 52 were returned back to the sender and 4 of the returned questionnaires were incomplete leaving the researcher with only 48 valid responses. According to Roscoe (1975), sample sizes larger than 30 and less than 500 are appropriate for most research thus this research was carried out although the response rate was quite low. Descriptive Statistical Technique was used to show the variables in terms of their frequency, percentages, standard deviation and mean. It was applied to analyze all the statements and questions from Section A and Section B of the questionnaire to draw statistical conclusions from the responses. The descriptive analysis techniques were used to answer research questions 1, 2 and 3.

FINDINGS AND ANALYSIS

Out of the 48 respondents, 14 were forwarding agents, 14 others were logistics companies and another 14 were logistics companies. This constitutes 87.6% of the total respondents. 79.2% of the respondents were local companies and the majority of them were wholly owned companies (87.5%). More than one third of the companies (37.5%) had employees between 1 to 30 workers and 31.3% of them had the most number of employees (more than 120). From the 48 responses received, 68.8% of the respondents had business dealings around Asia while only one served the Middle East markets. More than half of the total respondents (58.3%) were in their 6th to 15th year in business. 60.4% of the respondents used two banks while 31.3% used 3 banks in their daily operations. 70.8% of the respondents indicated that they preferred banks of local origin.

Table 2: Means and Standard Deviations for Dimension 1

Variables	Mean	Std.Deviation
Bank Strength	**4.26**	**0.343**
Bank's reputation	4.44	0.501
Innovative services	4.42	0.498
Reliability of personnel / staff	4.35	0.483
Knowledge of firm's business	4.31	0.511
Banking expertise	4.27	0.676
Size of bank's assets	4.25	0.565
Origin of bank (Local / Foreign banks)	4.08	0.647
Availability of branches abroad	3.98	0.758

The table above indicated that all the variables under the bank strength dimension showed a favorable mean which showed that these variables were important as criteria for them to choose the preferred banks. Almost all variable had a mean of more than 4 with the exception of the variable 'availability of branches abroad'.

Table 3: Means and Standard Deviations for Dimension 2

Variables	Mean	Std.Deviation
Customer Service	**4.17**	**0.330**
Safety of funds and confidence	4.69	0.468
Efficiency in correcting mistakes	4.63	0.489
Speed of service and decision making	4.48	0.505
Efficiency of personnel / staff	4.33	0.519
Friendliness of personnel / staff	4.27	0.610
Operating hours	4.27	0.610
Ample nearby parking facilities	4.21	0.544
Convenience of location	4.19	0.445
Prompt services	4.10	0.805
E-banking / Online banking	4.00	0.743
Attractiveness of branches	3.67	0.996
Effective advertising	3.25	0.601

Under the customer service dimension, the majority of the variables recorded a response of 4 and above which indicated that variables under this dimension were important in selecting banks. The highest mean recorded was for the variable ' safety of funds and confidence'. Two variables, effective advertising and attractiveness of branches had means of 3.25 and 3.67 respectively.

Table 4: Means and Standard Deviations for Dimension 3

Variables	Mean	Std.Deviation
Competitiveness with other banks	**4.15**	**0.550**
Flexibility in loan negotiations	4.44	0.542
Lending policy	4.21	0.713
Interest on deposits	4.04	0.824
Fee / interest charged on loans	3.92	0.942

For the third dimension, all except one variable had means of more than 4. This indicated that the variables under this dimension were important in bank selection. However, the variable 'fees/ interest charged on loans' recorded a mean of 3.92, which pointed out that the respondents were unsure whether this variable is important, or not to depict the competitiveness of a bank with other banks.

Table 5: Ranking of Variables

Variables	Mean	Ranking
Safety of funds and confidence	4.69	1
Efficiency in correcting mistakes	4.63	2
Speed of service and decision making	4.48	3
Flexibility in loan negotiations	4.44	4
Bank's reputation	4.44	4
Innovative services	4.42	6
Reliability of personnel / staff	4.35	7
Efficiency of personnel / staff	4.33	8
Knowledge of firm's business	4.31	9
Friendliness of personnel / staff	4.27	10
Operating hours	4.27	10
Banking expertise	4.27	10
Size of bank's assets	4.25	13
Ample nearby parking facilities	4.21	14
Lending policy	4.21	14
Convenience of location	4.19	16
Prompt services	4.10	17
Origin of bank (Local / Foreign banks)	4.08	18
Interest on deposits	4.04	19
E-banking / Online banking	4.00	20
Availability of branches abroad	3.98	21
Fees / interest charged on loans	3.92	22
Attractiveness of branches	3.67	23
Effective advertising	3.25	24

From Table 5, the variables with the highest mean were safety of funds and confidence, followed by efficiency in correcting mistakes and speed of service and decision making. This showed that in selecting which banks to patronize, international business operators rank safety of funds and confidence as the most important criteria that a bank should have. This indicated that the element of trust was very important to entice would-be customers to patron specific banks. Surprisingly enough, attractiveness of branches and effective advertising were the variables with lower means. This showed that customers would not choose a bank based solely on exterior factors and aggressive promotional activities.

Table 6: Ranking of Banks

Name of Bank	Frequency	Percentage (%)	Origin (L/F) *	Ranking
Maybank	23	47.9	L	1
Standard Chartered	14	29.2	F	2
HSBC	14	29.2	F	2
Affin Bank	12	25	L	4
AmBank	11	22.9	L	5
RHB Bank	11	22.9	L	5
BCB	10	20.8	L	7
EON Bank	10	20.8	L	7
Southern Bank	4	8.3	L	9
Alliance Bank	2	4.2	L	10
Citibank	2	4.2	F	10
UOB	2	4.2	F	10
Bangkok Bank	1	2.1	F	13
Hong Leong Bank	1	2.1	L	13
Public Bank	1	2.1	L	13

Note: * L = Local , F = Foreign

Table 6 lists all the banks that the respondents used and their rankings. Maybank, a local bank was the most preferred bank among the international business operators. It garnered 47.9% votes, which indicated that almost half of the respondents used Maybank in their business operations. The second and third spots went to foreign originated banks, Standard Chartered and HSBC. The two banks that were least preferred by the respondents were Hong Leong and Public Bank. This was apparent from the responses collected whereby only one response was gathered for each bank. Two banks, namely Bank of China and Bank of America, both foreign-originated banks were not preferred by any of the respondents.

DISCUSSIONS

Due to the competitive nature of the banking industry, it is imperative that banking institutions pay closer attention to what the customers really want. Thus, knowing the criteria customers, in this case, international business operators look for in a bank is critical to maintain a healthy relationship between both parties. From the findings, it is concluded that the most important criteria international business operators look for in a bank is safety of funds and confidence. No doubt the element of trust should be present in order for a business customer to patronize specific banks. This criterion is followed by the second highest ranking criterion namely efficiency in correcting mistakes, which brought us to the conclusion that customers want any errors to be corrected promptly as to not loose precious business time. The third important criterion in bank selection identified was the speed of service and decision making. It can be inferred here that the underlying reason for the importance of this criterion is that customers do not want their smooth-sailing business operations to be disrupted by glitches in terms of banking services. These hiccups will eventually affect the relationship between both parties and might be an underlying excuse to change provider. On the other hand, the bottom three least important criteria identified were effective advertising, attractiveness of branches and fees / interest charged on loans. This implied that promotional efforts, decorative factors and competitiveness with other providers were unimportant in bank selection. Comparing the means for all three dimensions, it is concluded that the first dimension, bank strength had the highest mean (4.26). Therefore, this possibly showed that almost all the variables under this dimension were important in bank selection. In addition, possibly, a bank's strength was the most important factor that distinguishes one bank from the other.

Tapping further into the identified criteria international business operators look for in selecting banks, I am of the opinion that since these companies' daily operations normally involves a lot of cross-border activities and delivery of goods to most parts of the world, it is highly relevant for them to put confidence and trust as the key elements in selecting banks. To them, these banks will act as middlemen for giving and receiving funds and relevant documents, such as Letter of Credits to and from other banks and from their clients. Therefore, it is

highly important for these operators to have confidence in their chosen banks. Furthermore, when dealing in a business environment where timing is everything, you need to find banks, which can deliver what they promise as and when needed. Any glitches will result in extra cost such as paying for demurrage; which is charges paid to the port for goods / vessel that are not unloaded within the specified time frame and paying extra for storage for goods which are not released promptly. It gets worse if the operators are dealing with perishable goods like foodstuff. When compared with a similar study by Edris (1997), the top three identified criteria deemed important among business customers were size of banks assets, efficiency of personnel and help in financial emergencies. Meanwhile, the lowest ranking determinants identified by Edris (1997) were effective advertising, interest on deposits and lending policy. Although the findings have more dissimilarities than similarities, one criterion remained the same. It showed that effective advertising were ranked the lowest in both studies. Comparing with another similar study by Nielsen *et al.* (1998), the most important criterion in selecting banks was the willingness of the bank to accommodate the customers' credit needs, followed by the efficiency of bank's daily operations and bank's knowledge of the company's business.

LIMITATIONS

There were several limitations to this study, which should be noted. First, given that the sample comprised of international business operators in Port Klang, Selangor, the results may not be generalize to other populations. Second, there is an imbalance in terms of local and foreign companies as respondents, which suggest that, further investigations for other relevant factors to be included in future researches. This imbalance would probably lead to 'Country-of-Origin' biasness. Third, since the Federation of Malaysian Manufacturers (FMM) e-directory did not indicate whether the company was actually the head office or only the branch, this might have an impact to the responses given because normally the head office will handle the selection of banks.

CONCLUSION

Hopefully , this study has managed to answer all its objectives and contributed some input to the body of the relevant literature. As a conclusion, the most important criteria international business operators in Port Klang, Selangor look for in a bank is the safety of funds and confidence. The least important criteria in bank selection is effective advertising. The most important dimension in bank selection is the bank strength factors. The most preferred bank is Maybank, followed by Standard Chartered and HSBC. It is recommended that a comparative study be conducted to determine the services considered important to business customers and compare the rankings of important services among different types of businesses. The business firms could be categorized according to nature of business, origin, size and so forth. Another area that could be further studied is on the intention, attitudes and social influence in bank selection in a specific culture.

Abstract
For many years, Profitability Index (PI) has been used extensively for the calculation of project return. Payback has a different implication in the performance appraisal world where it deals with the calculation of a duration required for a particular investment return. This paper presents an artificial decision-making tool, which is the fuzzy logic (FL) design. This is to link traditional variables of PI and payback. The usage of an engineering tool, LabVIEW FL toolkit in this work, integrates the two input variables, namely PI and Payback Period (PP) and generates an output. The associated output is the rating consideration for project investment. This method may reveal different degree in rating projects. FL concept will be discussed and the implementation will be shown graphically in this work.

INTRODUCTION

PI (Pike, 2003) indicates the ratio of the present value of benefits to cost, which takes into account the present value and capital investment into mathematical calculations. PI is evaluated in such a way, where a project's present value is divided by the capital invested. Greater value of this index is preferred. Payback is a project appraisal technique, which indicates the time period require to regain the initial capital invested in a project. When the yearly-accumulated return from the project is equal to the capital invested, the payback can be realized.

PI and payback are two different appraisal methods, which have different implications in terms of project return and project PP. To deal with sources of vagueness and imprecision, fuzzy theory may be employed as a useful tool for handling such conditions. Fuzzy uncertainty can have an effect on important decision (Jablonowski, 2000). Fuzziness can be found in many areas; particularly frequent in areas in which human judgment, evaluation and decision are important, as these are in investment selection projects (Isabel, 1989, P150).

Consider these two scenarios, firstly, a project that has a high PI ratio with a long PP, secondly, another project B that has a low PI ratio with short PP. What would be a better decision that a company would prefer in relation to the importance of PI and PP. Especially to determine the project rating precisely in wording of how "Good" or how "Bad" would then turn out to be "ambiguous". Fuzzy set theory enables a soft classification approach to account for uncertainties (Aydin, 2004). Project Rating (PR) can be used to illustrate the weighting of these variables. To rate a project, FL would be applied to generate the output based on the important analysis of the two input variables; PI and PP.

PI AND PP DESIGN

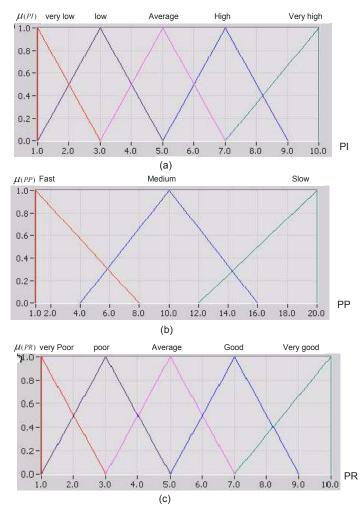
Bellman and Zadeh defined a decision set, which unifies a fuzzy objective (i.e. a fuzzy goal) and a fuzzy constraint given by a decision maker (Yuji, 2001). In this paper, PI and PP are denoted as two input variables and the project rating will be the output variable. In all fuzzy designs, fuzzification, inference process and defuzzification are three important stages.


Figure1: (a) - (b) show The Membership Functions Of Two Input Variables and (c) shows The Membership Function Of The Output Variable PR.

In the first step of fuzzification, membership function (MF) can be linguistically explained by individual sets such as very low, low, average, high and very high in figure 1. The linguistic term can be manipulated with fuzzy set theory and they can be interpreted as specific fuzzy number that allows us to perform the tradeoff analysis among various criteria [Juite, 2002]. All terms are assigned with membership degree in the range from 0 to 1. The PI is set within a range from 1 to 10 and PP has a range from 1 to 20 years. A project with 18 years PP would fall into 'slow' in the linguistic term as shown in figure 1(b). The crisp value of 4 in PI would be classified under fuzzy sets as slightly 'low' and slightly 'average'.

Table 1: Rating Rules Based For Projects

Rules	PI	PP	PR
1	Very low	Fast	Average
2	Very low	Medium	Poor
3	Very low	Slow	Very poor
4	Low	Fast	Average
5	Low	Medium	Poor
6	Low	Slow	Poor
7	Average	Fast	Good
8	Average	Medium	Average
9	Average	Slow	Poor
10	High	Fast	Very good
11	High	Medium	Good
12	High	Slow	Average
13	Very high	Fast	Very good
14	Very high	Medium	Good
15	Very high	Slow	Average

After two linguistic variables have been clearly defined, inference processing would be the next stage. The decision on the PR are highly dependence on the 'IF and THEN' rules. Table 1 shows the detailed rule-based, which is used for inference process. Output linguistic terms have individual sets defined as the following: very poor, poor, average, good and very good. For example, in rule 1: if PI is very low and PP is very fast, then, PR will be average etc. The rule-based formulation depends on human expertise and experience about this subject matter. If the project PI is 'High' and the PP is 'Slow', the project will be classified as 'Average'.

Project Evaluation Process

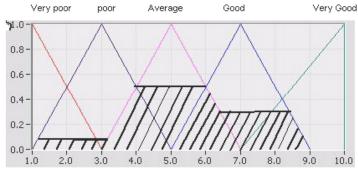
Defuzzification is the final stage of the entire fuzzy process. Figure 2 shows the linguistic terms that consist of 'very poor, poor, average, good and very good'. Under diverse combinations of PI and PP as crisp input values to fuzzy process, this would yield the different output crisp value after defuzzification. When a project has PI 5.5 and PP 13 years, the crisp output could be computed using mathematic equation, which is the stage of defuzzification.


Figure 2: Centre Area For Completed Project Rating Output

Shaded area in figure 3 shows the output of PR, when PI and PP is 5.5 and 13 respectively. To get crisp output value, it is necessary to calculate the aggregated average output as follows:

$$PR = \frac{0.5(5) + 0.3(7) + 0.1(3)}{0.5 + 0.3 + 0.1} = 5.44$$

PR is rated from minimum of 1 to a maximum of 10. The output, which yields a higher value, would be preferable. The result of 5.44 is considered an average project. Advance engineering software tool, LabVIEW and FL toolkit were utilized to assist in automating the calculation and fuzzy process for obtaining output values through these iterative procedures.

3-D Representation For Project Investment Assessment

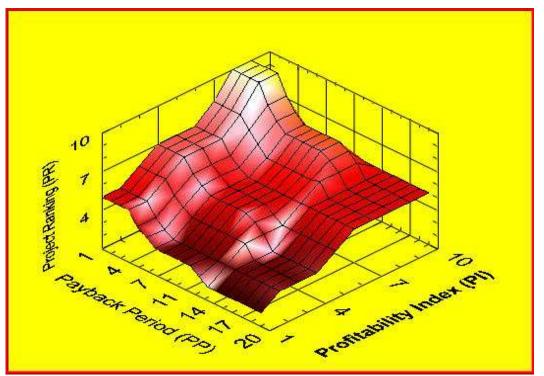
A three dimensional representation of project ranking (i.e. as a single output) versus payback period and profitability index is shown in the following figure 3. LabVIEW and Fuzzy Logic controller design toolkit were utilized to perform the entire fuzzification, inference and defuzzification processes. The data analysis and presentation is performed with this powerful graphical user-friendly software, which is widely used in engineering and science disciplines.


Figure 3: 3D Surface Plot Showing The Dependency Of The PI And PP And The Output Variable PR

A 3D surface plot is obtained and it shows the dependency of two inputs variable and the output variable. It shows the result of how individual variable will affect the crisp output value. A combination of high PI value and a low PP value, when input into this particular fuzzy logic design, will result and display peaks in this graphical output. This particular type of representation of 3D surface plot is useful, with clear visibility for investors considering project investment rating.

CONCLUSION

In this study, a Fuzzy Logic tool was utilized to investigate the evaluation of projects based on two linguistic input variables namely, profitability index and payback period. Evaluation and decision-making based on project rating would be easy using this approach. In evaluating project investment rating, the effort may be arduous in handling

substantially huge amount of different combinational values from different input variables. The use of FL could ease this complexity and data representation. The capability of FL is not limited to 2 variables only. In principle, this intelligent decision making tool is scalable to multi-input variables, especially for a complex project investment that has multiple input variables rating consideration. In conclusion, this paper presents a useful tool utilizing an artificial decision-making tool, the LabVIEW Fuzzy logic design for the purpose of project investment rating.

Testing the Liberal and Social Feminist Theories:
A Study on Small Sized Enterprises

Rossazana Ab. Rahim
Tan Kok San
Faculty of Economics and Business
Universiti Malaysia Sarawak
94300 Kota Samarahan, Sarawak, Malaysia

ABSTRACT

The purpose of this study is to ascertain the similarities and differences among female and male entrepreneurs in small-scaled enterprises based on the theory espoused by the Liberal and Social Feminist. The study also attempts to investigate the main hypothesis that small enterprises owned by female generally under-perform male owned enterprises on a variety of measures such as capital, sales and number of employees. The study tests five hypotheses and finds support for liberal feminist theories (female entrepreneurs are les successful, leave fulltime education earlier and have fewer years of working experience than male entrepreneurs). On the other hand, with respect to the social feminist theory, the study provides support to the difference characteristics possessed by female and male entrepreneurs but shows mixed evidence of the motivational factors for the business set-up.

INTRODUCTION

There has been a huge growth in studies on various aspects of entrepreneurship. The focus of these studies has been on observing and describing the characteristics of the entrepreneurs (Chu, 2000 and Dhaliwal, 2000); the problems face by the entrepreneurs (Coleman, 2002); their motivations (Lee, 1997; Orhan & Scott, 2001 & Scott, 1986); the profile and typology of the entrepreneurs (Cromie & Hayes, 1988; Ufuk & Ozgen, 2001; Stevenson, 1986 & Hisrich & Brush, 1987); the differences between women and men entrepreneurs (Mahadea, 2001; Mukhtar, 2002; Ljunggren & Kolvereid, 1996; Catley & Hamilton, 1998; Du Rietz & Henrekson, 1999; Mills & Voerman, 1999 & Rosa, Carter & Hamilton, 1996) as well as discussing the institutional factors that encourage entrepreneurship (Welter, 2002 & Winn, 2000). Thus, the study of entrepreneurs has occupied a position on the research agenda and academic institutions in a variety of disciplines.

Basically, entrepreneurship is defined as the process of creating a business with combination of necessary skills, time and effort by taking responsibility on the development of the business as well as financial, physical and social risks to gain the monetary rewards and personal satisfaction (Hisrich and Brusch, 1986). Schumpeter (1934) ties entrepreneurship with innovation by defining entrepreneurship as "carrying out new combinations". Contrary with the remarks he made prior, Schumpeter claims that he does not define an entrepreneur as an innovator but says he "has no objection to some such expression". Meanwhile, Drucker (1985) defines entrepreneurs as those who shift economic resources from lower level into a higher productivity with greater return.

Gartner (1985) defines entrepreneurship as the creation of new organizations and mentions that arguments over the definitions on entrepreneur and entrepreneurship have hampered research progress. In 1990, he adds that a consensus on entrepreneurship definition is hardly to be reached. He recommends that a specific definition should be carefully developed to suit with the purpose of the respective research. In this study, women entrepreneurs are defined as women owner managers. Their ownership may be acquired through their own creation, through inheritance or be jointly established with or without family or non-family members and they must be actively involved in the business (Chu, 2000).

Recently, research on sex and gender differences in entrepreneurial characteristics and performance has continues to receive a considerable amount of attention. The empirical findings and recommendations reported are diverse and sometimes contradictory. Many studies suggest that there are few differences between the experiences and needs of female and male entrepreneurs while other studies seem to confirm the coexistence of male and female entrepreneurs in traits. Brusch (1992) study in U.S. examines a great many aspects of female entrepreneurship, which found to be underperformance than the male counterparts by conventional production, employment, profitability and other performance indicators. In support to that, Rosa, Carter and Hamilton (1996) study in Britain

find that female entrepreneurs tend to be less successful than their male counterparts in terms of conventional economic performance measures such as profitability and growth in sales, value added and employment. Lipper (1988) states that an entrepreneur can be successful without achieving monetary profits if he defines success other than monetary measures. Thus, this study springs up from the basic question: 'Are women entrepreneurs difference from men counterparts?'

There have been numerous studies worldwide on performance of women entrepreneurs with comparison to male counterparts but this area is relatively unexplored in Malaysia case despite the fact that women have significantly contributed to the Malaysian economy. According to 2000 population census, the share of women employed is found highest in production and related workers sector (22.6 per cent), followed by clerical and related works (17.5 per cent), service workers (17.4 per cent), agriculture workers (14.8 per cent), professional, technical and related workers (13.5 per cent), sales and related workers (12.1 per cent) and lastly, administrative and managerial workers (2.2 per cent). In tandem to that, Malaysian government is taking continuous efforts towards the involvement of women in income-generating activities. Various women entrepreneur and industry association are formed, generally to serve as a platform for women entrepreneurs to establish networks and exchange information and experiences as well as to conduct training programs, seminars, and workshops on motivation, leadership and entrepreneur development. (Malaysian Eighth Plan, 2002). Taking awareness of the government policy in encouraging the involvement of women in business calls for this study to be undertaken in order to obtain a better understanding of this group of people who had generously contribute to the Malaysian economy.

The study will concentrate on the women entrepreneurs involve in small sized enterprises. According to Hashim and Wafa (2002), small and medium sized enterprises are created by entrepreneurs and they are responsible for making decisions and solving problems in their organization. These entrepreneurs tend to exhibit certain characteristics. Small enterprises represent particularly appropriate opportunities for women entrepreneurs, as they respond flexibly to entry, change and innovation. Although it can be dynamic, the small sector is all too often marked by outdated and inefficient practices and technologies. As a result, small enterprises tend to operate far below their productive capacity. This relates especially to women, as despite good levels of education and high participation in the labor market, they become entrepreneurs on average twice less often than men (UNECE, 2002).

This study aims to explore the nature and characteristics of gender determinants in the performance of small scaled enterprises. This study, which motivates from the liberal and social feminist theories, attempts to explore the underlying factors that lead female and male entrepreneurs to enter the entrepreneurship field as well as to investigate the personal traits of those entrepreneurs.

LITERATURES SURVEY

Most of the theories of entrepreneurship are widely created by men and indeed applied to men (Holmquist and Sundin, 1988). But, nowadays, the theories are broadly used to evaluate women entrepreneurs' performances (Carter and Weeks, 2002). According to Chell and Baines (1998), the male performance is seen as a norm, and female performance tends to be under judged against this norm. Thus, if female behaviours are no match to male traits, women are unlikely to be well equipped to perform as an entrepreneur within the definition.

Meanwhile, according to Brusch (1992) out of 57 gender's studies reviewed, 39 percent (%) do not base on any theories and majority of the studies concluded that the female are under performance than male by using a single performance measurement such as financial gain. In addition, Mirchandani (1999) emphasizes the need of adapting the gender-based theories into the small and medium enterprises researches in order to change both male and female perspectives. He further states "approaches to women and entrepreneurship would benefit greatly from theoretical insight on the gendered processes in work settings developed within feminist theory". Fisher, Reuber and Dyke (1993) respond to the need by developing liberal feminist and social feminist theories, which is more systematic knowledge base.

Liberal and social feminist theories are broadly used to understand, explain and study the inequity social status of women in society. Most of the liberal feminist literatures study the differences of female and male entrepreneurs with respect to business performance and segregation of social opportunities such as education and experience. On the other hand, social feminist studies are carried out to investigate the similarities and differences between women and men entrepreneurs with respect to entrepreneurial motivation and personal characteristics (Carter and Williams, 2003).

Liberal feminist theory is seen as the root of liberal political philosophy that espouses the basic belief of that human beings are equal, essentially rational and self-interest seeking agents (Fischer et al., 1993). The theory does not recognize any inherent gender differences and any physical differences exist between men and women are assumed to be irrelevant to rationality. Besides that, rationality is also assumed to be pure mental capacity and held equity within every person regardless of the gender. Thus, the theory states that women are as equally capable of rationality as men but they are segregated from social opportunities such as education and experience. According to Mills and Voerman (1997), the main reason fostering the differences between men and women is sexism, which consists of a blend of prejudices and discriminatory practices against women that in turn influence their social purposes.

On the other hand, social feminist theory is a theory of oppression, which views women as oppressive, unequal, difference and restrain due to the socialization and maltreated of the patriarchal system. With contrast to the liberal feminist theory, it explains that female and male are indeed difference due to the socialization process they experienced. The theory categorized male and female entrepreneurs as two separate groups, each with an equally valid, but they are distinct in the way of thinking and rationalizing. Social feminist theory also posits that the differences between female and male exist from the earliest moments of life which are due to the fundamentally difference ways of viewing the world. In addition, the theory assigns that the female and male entrepreneurs are subject to experience difference socialization processes due to their gender. Those difference socialization processes will lead them to be difference in respect of psychological characteristics such entrepreneurial motivations and personal traits.

With regard to education, Fischer et al. (1993) shows no support to the liberal feminist theory that states the female entrepreneurs have less access to relevant education than male counterparts. They recommend that the only significant difference appears where male entrepreneurs tend to have more production-related business educational than female. On the other hand, they provide support to the theory when they find out that female entrepreneurs tend to have less prior experience, as men are more likely to have more experiences in the business start up. With respect to psychological traits, they state that there are gender differences entrepreneur's traits such as self-actualisation, self-confidence, compassion and risk taking propensity as well as differences in motivations.

In parallel to liberal feminist theory, Mills and Voerman (1997) find out that female entrepreneurs in Sweden and Netherlands tend to operate a smaller business than male counterparts. They also highlight that although women entrepreneurs left the formal education average four years earlier than male counterparts, but they still have less relevant work experiences. They stress that this is due to the female entrepreneurs always switching job between sectors or they do not start working immediately after leaving the school due to marriage and children rearing. They concludes that the reason why women entrepreneurs are less capable to realize their full potential than men entrepreneurs is due to segregation from accessing essential social opportunities such as education and experience. On social feminist aspect, they find out that the psychological characteristics of the female respondents are almost the same as male counterparts.

According to Watkins and Watkins (1983), the male entrepreneurs are more likely to have relevant entrepreneurial education and prior experience compare to female counterparts that will result in low performance of female entrepreneurs as compared with male entrepreneurs. In opposite theory, they find out that men entrepreneurs are risk gamble and majority of them established their businesses due to the personal factors such as self-independent and autonomy while most of the female counterparts are motivated by the financial factors.

Hisrich and Brush (1986) states that the motivations for the female entrepreneurs to start up the business are job satisfaction, independent, achievement and to survive. In addition, Hisrich et al. (1996) confirm that men respondents are more insolence, selfish and hard working, while the female respondents are more active, inventive and effective. Sexton and Bowman-Upton (1990) further stress that men entrepreneurs have higher energy level than female counterparts on value placed on autonomy and risk taking propensity but, the female entrepreneurs have higher willingness to accept change. Lastly, the study conclude that there is a slightly difference between female and male entrepreneurs with regard to psychological characteristics.

The study conducted by Lee and Rogoff (1997) attempts to explore the similarities and differences between female and male entrepreneurs in terms of psychological characteristics such entrepreneurial motivations, attitudes and satisfactions. They point out that the self-actualisations such as goals of maximizing personal skills, contributing to society and gain respect and reorganisation are the core motivations that pulled the female entrepreneurs to start up the business. But, they conclude that the female entrepreneurs' motivation to start up the business was slightly difference from men counterparts.

In a local study done by Ismail and Joned (1999) on 109 Malay women entrepreneur, they find out that 42.4 percent (%) of respondents are predominant in service-oriented business, 40% have more than RM 100,000 total paid up capital, 66% have less than RM 200,000 value of sales per annum. In addition, they also state that 35% have previous working experience in administration, education, finance, public relations and business.

Hence, from the brief summary above, we can conclude that the result of empirical study on liberal and social feminist theories is mixed, thus provides a platform for further discussion.

HYPOTHESES

The study is mainly extending several previous studies that apply liberal and social feminist theories. Therefore, this section presents the hypotheses that are formulated from the previous studies (Fischer, Reuber and Dyke, 1993; Mills and Voermen, 1997 and Du Rietz and Heurekson, 1999).

Hypothesis 1: Female entrepreneurs are less successful than male counterparts.
Hypothesis 2: Female entrepreneurs posit difference education background compare to male counterparts.
Hypothesis 3: Female entrepreneurs have less working experience than male counterparts.
Hypothesis 4: Female entrepreneurs have difference entrepreneurial motivations than male counterparts.
Hypothesis 5: Female entrepreneurs have difference personal traits than male counterparts.

DATA ANALYSIS

Data was collected from the respondents who are the owner of small enterprises. For the purpose of the study, small-sized enterprises are defined as a firm with an annual turnover of not less than RM10 million and employ full time employees of not exceeding 50 persons (Hashim and Wafa, 2002). A total of 300 sets of questionnaires were distributed, where only 159 questionnaires were received, with 151 useable responses which gives a net response rate of 50.3 per cent. Out of 151 net responses, 75 responses were from male and 76 sets from female entrepreneurs. These response rates are considered low despite the fact that a follow-up call was made two week after the questionnaires were mailed in an effort to increase response rate. Coefficient Alpha value for the pilot study that carried out by interviewing 10 entrepreneurs in SMEs, Kuching is 0.9076. According to Israel (1992), an alpha of 0.8 is generally considered good to indicate the strong internality consistency in index. Thus, the scales of scores for the questionnaire are highly reliable and all of the items listed are consistent in measuring the variables of study.

This study is carried study out using a survey methodology. A questionnaire has been developed and included a combination of scaled, multiple choice, open-ended and rank order questions. The questions formed are used to assess the following; business data, business performance, motivation for starting a business; characteristics of the entrepreneurs, and selected demographic characteristics. To measure the entrepreneur's business performance, the study used three indicators such as sales, capital and number of employees that includes measure of changes over four years as formulated in Fischer, Reuben & Dyke (1993). Meanwhile, this study adopted the dimensions used in Hisrich and Brusch's study (1986) to measure the personality characteristics of the entrepreneurs. Three items have been selected which are self-independent, willingness to take a risk and self-confidence. On the other hand, this study used three types of motivation to measure the reason for entrepreneurs to start-up their business, which are financial, lifestyle and social recognition motivation.

Descriptive statistics such as means, standard deviations, and percentage will be used to record and analyze the respondents' demographic characteristics with respect to the company's profiles. To test the hypotheses highlighted in the study, λ^2 tests comparing means for women and men entrepreneurs on the performance indicators, characteristics and motivation and performance are conducted.

RESULTS AND DISCUSSION

Business Activities

As shown in Table 1 below, female enterprises are found higher in food, cloth and services business than the male entrepreneurs who involved more in manufacturing and computer business. In service industries, female involved

more on feminine-related services such as saloon, beauty centre, boutique and floweriest; while male engaged more in transportation and car servicing business.

Table 1: Type of Business Activities of Female and Male Entrepreneurs

Business activities	Male		Female	
	Frequency	Percentages (%)	Frequency	Percentages (%)
Manufacturing	14	18.67	1	1.32
Cloth	4	5.33	14	18.42
Food	13	17.33	36	47.37
Service	19	25.33	20	26.32
Retail	7	9.33	0	0.00
Computer	10	13.33	1	1.32
Others	8	10.67	4	5.26
TOTAL	75	100	76	100

Female and Male Entrepreneurs' Business Performance

The variables of capital, sales and the total number of employees are selected to assess the business performance of the entrepreneurs. The findings and results in this section are used to answer the following hypothesis:

Hypothesis 1:   Female entrepreneurs are less successful than male counterparts.

In an independent sample t-test for capital variable by respondents' gender as illustrated in Table 2 below, the p value (0.003) is less than 0.01 of significant level which explains that the total amount of capital is closely related to the gender of respondents and there is a significant difference between female and male respondents with regard to initial capital as well as annual capital.

Table 2: Comparison of Female and Male Entrepreneurs on Capital Variable

Capital (RM)	Male		Female	
	Mean	Standard Deviation	Mean	Standard Deviation
Initial capital	16 431.68	20 131.72	5 297.30	5 053.85
2000	37 817.95	42 174.99	14 902.56	20 356.61
2001	37 705.13	42 068.19	14 680.00	20 143.18
2002	38 474.36	42 368.83	14 855.00	20 110.22
2003	38 705.13	42 264.47	14 885.00	20 178.24

Note: A λ^2 test indicates a significant difference in capital variable between female and male respondents ($\rho = 0.03$)

The annual sale variable is one of the indicators that are used to assess the business performance of the respondents as illustrated in Table 3 as follows.

Table 3: Comparison of Female and Male Entrepreneurs on Sales Variable (RM)

Sales (RM)	Male		Female	
	Mean	Standard Deviation	Mean	Standard Deviation
2000	68 033.33	54 569.320	29 371.79	25 045.63
2001	67 905.13	54 353.013	28 912.50	24 892.52
2002	68 848.72	54 915.63	28 912.50	24 892.52
2003	69 246.15	55 277.74	28 812.50	24 722.44

Note: A λ^2 test indicates a significant difference in capital variable between female and male respondents ($\rho = 0.02$)

In a λ^2 test, value of 0.002 indicates that there is a significantly difference between female and male respondents with regard to the annual sale in 2000 to 2003.

The findings with regard to the total number of employees employed by female and male entrepreneurs are illustrated in Table 4 below. In a λ^2 test, ρ value less than 0.1 illustrates that there is a merely significance difference between female and male respondents with respect to total number of employees.

Table 4: Comparison of Female and Male Entrepreneurs on Employees Variable

Employees (Number)	Male		Female	
	Mean	Standard Deviation	Mean	Standard Deviation
2000	4.69	8.627	1.26	1.371
2001	4.87	8.606	1.25	1.354
2002	4.97	8.601	1.28	1.339
2003	5.23	8.616	1.22	1.349

Note: A λ^2 test indicates a significant difference in number of employees' variable between female and male respondents (ρ = 0.05)

With regards to the liberal feminist theory, the findings of this study have clearly revealed that the female entrepreneurs in small-sized enterprises have grasp lower annual sales, operate smaller firm with lower initial capital and employ less number of workers as compared to male counterparts. Besides that, this study also recommends that the female entrepreneurs tend to be underrepresented in manufacturing and construction sectors compare to male counterparts.

Female and Male Entrepreneurs' Education Background

The education backgrounds of female and male respondents are measured in two aspects, namely highest formal education level and the field of expertise. The findings and results are used to ascertain the hypothesis that related to liberal feminist theory. The hypothesis is as following:
Hypothesis 2: Female entrepreneurs will have difference education background compare to male counterparts

Table 5 and 6 show the comparisons of females and males with respect to education and field of expertise. It indicates that there is a significant sex differences in education and expertise. With respect to education, male have higher educational level with more than 70% of them have at least SPM/SPMV certificate. On the other hand, more than 60% of female entrepreneurs have at most SRP/PMR certificate with 17.11% of them did not receive any formal education as compared to male with only 2.67%.

Table 5: Female and Male Entrepreneurs' Highest Formal Education Level

Educational Level	Male		Female	
	Frequency	Percentages (%)	Frequency	Percentages (%)
No	2	2.67	13	17.11
Primary School	6	8.00	21	27.63
SRP/PMR	14	18.67	12	15.79
SPM/SPMV	23	30.67	18	23.68
STPM/Certificate/Diploma	19	25.33	12	15.95
Bachelor/Master Degree	11	14.67	0	0.00
Total	75	100	76	100

Note: A λ^2 test indicates a significant difference in educational level between female and male respondents (ρ = 0.03)

As shown in Table 6, more than 67% of the female entrepreneurs failed to identify their field of expertise with personnel recorded the highest field possessed by female (21.05%). Male are found to be more expert in marketing, accounting as well as information technology as compared to female counterparts.

Table 6: Female and Male Entrepreneurs' Field of Expertise

Field of Expertise	Male		Female	
	Frequency	Percentages (%)	Frequency	Percentages (%)
No	24	32	51	67.11
Marketing	11	14.67	2	2.63
Personnel	2	2.67	16	21.05
Accounting	8	10.67	3	3.95
Information Technology	8	10.67	2	2.63
Technical	22	29.33	2	2.63
Total	75	100	76	100

Note: A λ^2 test indicates a significant difference in the field of expertise between female and male respondents ($\rho = 0.05$)

Female and Male Entrepreneurs' Working Experience

Table 7 below illustrates the results of previous working experience by female and male respondents. The result in this section is used to ascertain the following hypothesis:
Hypothesis 3: Female entrepreneurs have less entrepreneurial working experience than male counterparts.

Table 7: Female and Male Entrepreneurs' Working Experience

Working Experience	Male		Female	
	Frequency	Percentages (%)	Frequency	Percentages (%)
No	9	12.00	19	25.00
Government Sector	13	17.33	4	5.26
Private Sector	50	66.67	28	36.84
Others	3	4.00	25	32.89
Total	75	100	76	100

Note: A λ^2 test indicates a significant difference between female and male respondents ($\rho = 0.002$) with respect to previous working experience

Female and Male Entrepreneurs' Entrepreneurial Motivations

The findings and the results in this section are used to ascertain the hypothesis that related to social feminist theory. The hypothesis is as following:
Hypothesis 4: Female entrepreneurs will have difference entrepreneurial motivations than male counterparts

Table 8: Female and Male Entrepreneurs' Motivation

Type of Motivation	Male	Entrepreneur	Female	Entrepreneur
	Means	Standard Deviation	Means	Standard Deviation
Financial Motivation[a]	2.61	1.064	2.04	0.799
Lifestyle Motivation[b]	3.56	1.145	2.17	0.748
Social Recognition Motivation[c]	2.30	0.883	3.55	1.072

Note: A λ^2 test indicates a significant overall difference between female and male respondents with respect to motivation of entrepreneurs
[a] $\rho = 0.037$;   [b] $\rho = 0.001$;   [c] $\rho = 0.000$;

The results provide mixed support to the hypothesis where female and male entrepreneurs are indifference in financial motivation but for lifestyle and social recognition motivation, there are significant differences between the genders.

Female and Male Entrepreneurs' Personal Traits

The similarities and differences between female and male with respect to personal traits are measured on three aspects: self-independent, risk taking propensity and self-confidence. The result is used to ascertain the hypothesis of social feminist theory as follows.

Hypothesis 5: Female entrepreneurs will have difference personal traits than male counterparts

Table 9: Female and Male Entrepreneurs' Characteristics

Type of	Male	Entrepreneur	Female	Entrepreneur
Motivation	Means	Standard Deviation	Means	Standard Deviation
Self Independent[a]	2.56	0.818	2.74	0.966
Risk Taking[b]	2.20	0.758	3.60	0.848
Self Confidence[c]	2.17	0.733	3.31	0.863

Note: A λ^2 test indicates a significant overall difference between female and male respondents with respect to personal traits
[a] $\rho = 0.000$;   [b] $\rho = 0.001$;   [c] $\rho = 0.002$;

The table illustrates that female entrepreneurs are difference from male counterparts with respect to personal characteristics. Male entrepreneurs are more self-confidence, self-independent and risk-taking propensity than female counterparts.

CONCLUSIONS

Given the importance of entrepreneurial success to organizations primarily, there is a need to determine how gender of the entrepreneur is related to entrepreneurial success. This study hopes to help particularly small-scaled entrepreneurs to understand the role of relevant performance in determining their success or failure. This increased understanding will allow them to be able to exert influence over others more effectively. The contribution of the study expects to shed some light on one of the underlying success factors of entrepreneurs to help them to compete more effectively in the competitive market, which has to date still lack in Malaysia context. Besides, it will be interesting to see the moderating effect of gender on certain performance indicators.

Policy makers should give more focus to the differences between female and male entrepreneurs when creates and designs entrepreneurship assistance programs. Those potential programs need to be tailored by taking the differences into account. In order to increase the performance of female entrepreneurs, the policy maker should create, design and implement more specialized training programs and consulting, specifically targeting women entrepreneurs at various stages in their business careers. Besides that, the policy maker should also taking initiatives to reduce the risk and expense of making smaller loans by promoting support services such as access to capital and credit specifically targeting women entrepreneurs. In addition, the policy maker is recommended to promote innovative incentives such as tax credits to increase the growth of female entrepreneurs, and improve the recognition of service-based businesses in order to increase the existing number of female entrepreneurs. While, female entrepreneurs are recommended to furnish themselves with new knowledge in the field such as technical, information technology and financial in order to be more competitive and well equipped. In order to increase their ability to compete, they should also be more independent and confident and be a moderate risk taker when operating the business.

Sales Promo-Tools And Product Trial

Nelson Oly Ndubisi
Chiew Tung Moi
Universiti Malaysia Sabah
Locked Bag 2073
88999 Kota Kinabalu, Sabah, Malaysia

Abstract

Various sales promotional tools (promo-tools) have been employed by marketers over the years to generate sales for their offerings. The use of coupon, price discount, free sample, bonus pack, and in-store display are examples of sales promotion strategies adopted by organizations to generate product trial and repurchase. Although most of these tools are used very frequently in Malaysia, there is still very poor understanding of their impact on product trial among researchers and practitioners who deploy these strategies. The current research is an attempt to unveil the influence of coupon use, cash discount, free sample, bonus pack, and in-store display on product trial among Malaysia consumers. Randomly selected consumers in Kota Kinabalu, Sabah were surveyed using structured questionnaire. A total of 312 usable responses were received and analyzed. The results show that price discount, free sample, bonus pack, and in-store display are robust determinants of product trial. Coupon is not. Details of the findings and their implications are discussed.

INTRODUCTION

Blattberg, and Neslin (1990, p.15), have mentioned that sales promotion expenditures have grown rapidly in recent years, even advertising remains an important promotion tool. And the field of sales promotion has attracted increasing attention from both executives and researchers in recent years. This growing interest is the result of the increasing importance of sales promotion activities in marketing strategy. According to Gilbert and Jackaria (2002), sales promotion consists of a wide variety of short-term tactical promotional tools aimed at generating a desired response from customers. There is a large body of literature on consumer response to sales promotions (e.g., Bawa & Shoemaker, 1987 and 1989; Gupta, 1988; Blattberg & Neslin, 1990; Leone & Srinivasan, 1996; Huff and Alden, 1998).

Though these studies have provided important insights into the effects of sales promotions, their usefulness in predicting the effects of sales promotions on product trialability of consumers is limited as too much emphasis has been placed on coupons at the expense of other equally important promotional tools. Thus, very little work has been done to investigate the effect of sales promotional tools such as free sample, bonus pack and in-store display on product trial. Therefore, the purpose of this current work is to integrate existing research and extends our understanding of consumer response to sales promotions. More specifically, it examines the degree to which sales promotion variables such as coupons, price discount, samples, bonus packs, and in-store display can predict product trial.

LITERATURE REVIEW

There are large numbers of studies addressing the question of how promotions affect individual purchase behaviour. Before a review of these studies, it is germane to understand the meaning of the term sales promotion.

Definition of Concepts

According to Shimp (2003), sales promotion refers to any incentive used by a manufacturer to induce the trade (wholesalers, retailers, or other channel members) and/or consumers to buy a brand and to encourage the sales force to aggressively sell it. Retailers also use promotional incentives to encourage desired behaviours from consumers-come to this store rather than a competitor's; buy this brand rather than another; purchase larger quantities; and so

on. Sales promotion is more short-term oriented and capable of influencing behaviour. Totten & Block (1994) stated that the term sales promotion refers to many kinds of selling incentives and techniques intended to produce immediate or short-term sales effects. Typical sales promotion includes coupons, samples, in-pack premiums, price-offs, and so on.

Fill (2002) defined coupons as vouchers or certificates, which entitle consumers to a price reduction on a particular product. The value of the reduction or discount is set and the coupon must be presented when purchasing the product. Coupons are a proven method by which manufacturers can communicate with consumers and are a strong brand-switching device. Gardener and Trivedi (1998) wrote that coupons have been used as a major promotional tool for years as a means of offering the consumer a one-time reduction in price and building brand awareness and loyalty as well. In fact, coupons have the potential to induce brand switching and induce purchase, indicating that consumers are influenced by the discount stated in the coupon. Fill (2002) stated that discount is the simplest technique to offer a direct reduction in the purchase price with the offer clearly labelled on the package or point of purchase display. By definition, sampling includes any method used to deliver an actual- or trial-sized product to consumers. According to Pramataris, Vrechopoulos, and Doukidis (2001), sampling is the activity of offering small quantities of product to consumers for free, in order for them to try it and potentially buy it. Gardener and Trivedi (1998) wrote that bonus packs are offers by the manufacturer that add value to the product by offering additional product at the regular price. According to Percy, Rossiter, and Elliott (2001), bonus packs do create an immediate incentive to buy. And Seibert (1996) stated that manufacturers like bonus pack because they increase brand trial, switching and stocking up. Percy, Rossiter, and Elliott (2001) wrote that display promotions could be an important part of an integrated marketing communication programme. Good display material leads to better attention, especially important for brands driven by recognition awareness and increase recognition at the point of purchase (trial).

Chandon, Wansink, and Laurent (2000) indicate that sales promotion may be attractive for highly promotion prone consumers for reasons beyond price savings. These highly promotion prone consumers may switch brands to receive "special" deals that reflect and reinforce their smart shopper self-perception. The highly promotion prone consumers might try a new product that have promotion.

Product trial involves actually trying or using a product (Kardes, 1999). According to Peter and Olson (1996), trialability refers to the degree to which a product can be tried on a limited basis or divided into small quantities for an inexpensive trial.

Sales Promotion as a Determinant of Product Trial

Banks (2003) wrote that with sales promotion, brands have a chance to quickly affect consumer choice and behaviour by adding value through an on-pack offer, by achieving incremental display or by encouraging trial via sampling and/ or couponing. According to Schindler (1998), a price promotion that is designed to evoke attributions of responsibility could be expected to appeal to consumers more than one that does not evoke such attributions, and thus have a greater ability to create product trial of consumers.

Sales promotional tools such as coupons, discount, and free samples used strategically in various industries not only increase brand awareness, but also encourage consumers to try new products. For example, a manufacturer might utilize coupon incentives to encourage consumers to try the "new flavoured product X," enabling them to try the new flavour at a discounted price, instead of buying the same flavour they normally do at full price. Therefore, this incentive may reduce consumers' perceived risk associated with trying a new, less-familiar product for the first time (Blackwell, Miniard, and Engel, 2001).

Blackwell, *et al* (2001) described that new products are more apt to succeed when consumers can experiment with or try the idea on a limited basis, with limited financial risk. Therefore, sales promotion such as sampling, couponing, and trial-sized products are useful to induce the trial of products. For example, Procter & Gamble and General Foods give millions of new products away each year to make trial easy without economic risk to the consumer. However, Gilbert and Jackaria (2002) found that a free sample as a promotional offer had no significance on a consumer's reported buying behaviour.

Robinson and Carmack (1997) stated that coupons have been used to produce trial. According to Cook (2003), coupons are easily understood by the consumer and can be highly useful for trial purchase. "With more than 80% of

the American population in all demographics using coupons, marketers know that a strong coupon strategy is one of the most effective ways to directly motivate trial," said Charles Brown, vice president of marketing for NCH Marketing Service co-chair of the Coupon Council (Press Releases, 7/8/2003). But, in Gilbert and Jackaria (2002) findings, coupon is ranked last as the promotional least widely used by consumers and least influence on product trial.

The study by Wayne (2002) about new consumer research on three recent coupon programs showed that the promoted brands gained incremental sales through increased trial and subsequent non-coupon purchases. In the research it was found that six months after receiving one of these coupon offers, consumers were between two and five times more likely to have bought and used the promoted brand in the past than were a control group of similar consumers who had not received the coupon. Consumers who received the coupon offer were also twice as likely to indicate that they would buy the promoted brand in the future. Wayne observed that coupon offers can generate product trial and increase market share and brand sales. Moreover, coupons also can improve the future brand purchase intentions of consumers who receive the offers and build brands by building sales and market share, as well as by defending against competitive promotional activity

The coupon is the most common form of menu discounting and a generally accepted belief is that coupons contribute to short-term sales but are no substitute for a long-range advertising plan. However, coupon can be used to attract new customers to try and then will return later to pay full price for repeat purchase (Nation's Restaurant News, 1985). But, at worst, coupons maybe not encourage consumers to repeat purchase by paying full price. The customers maybe waiting until the next coupon is received to frequent the store (Nation's Restaurant News, 1985). From a study of supermarket shoppers, Cheong (1993) found that supermarket coupons increase the number of items bought but not increasing the total amount spent. The results of consumer surveys indicated that 91 percent of consumers believe coupons cause higher retail prices (Advertising Age, 1988).

Price promotion does influence new product trial (Brandweek, 1994). According to Ehrenberg *et al.* (1994), the short-term peaks in sales were due primarily to purchases made by occasional users of a brand rather than by new customers. Furthermore, the study concluded that these occasional users, after taking advantage of the price reduction, would most likely return to their favourite brands in their portfolio rather than buy the promoted brand at full price.

Free sample is another important promotional tool often used by marketers. Marketing manager recognize the importance of product trial and direct behavioural experience with a product. They often mail free samples of products to consumers so that consumers can try the products for themselves, rather than just hear about the products (Kardes, 1999).

Lee (1963) mentioned that factory bonus pack is used to increase consumer trial of the brand. Gardener and Trivedi (1998) wrote that larger package size and accompanying advertising of the offer tend to make the promotion noticeable. Since more of the product is included at no extra cost, consumers can be persuaded to buy the product if they feel it represents a deal that produces the greatest value for their money. According to Gilbert and Jackaria (2002), packs with "buy-one-get-one-free" may not increase brand awareness before trial purchase because the customer will only come across the product once in store (unlike samples or coupons). However, the promotion is noticeable thus facilitating brand recognition and brand recall for future purchases. Since an additional amount is given for free, consumers may be persuaded to buy the product if they feel it represents a fair deal that provides value for money.

Ong, Ho, and Tripp (1997) indicate that consumers appeared to be slightly sceptical of the bonus pack offer, but somewhat more trusting of the price and quantity claimed. In other words, believability of the bonus pack offer was weak. However, they would likely buy one bottle and not buy more than one bottle. This happen because consumers suspect that manufacturers do raise prices slightly in conjunction with bonus pack offerings. Therefore, Ong, Ho, and Tripp suggested to leave a few of the non-bonus packages (old package) on the shelves to facilitate comparisons with the new bonus pack offer in terms of quantities and the prices to persuade consumers to purchase the product and indirectly persuade consumers to try the product.

According to the trial and repeat model mentioned by Thomas (1993), it is generally assume that of all potential buyers in a given time period, only those who are aware of the new product could potentially try it (trial), and only those who try it could potentially buy it again (repeat). Thomas also assumed that the magnitude of planned distribution and promotion expenditures (advertising, sales promotions, sales force, and so on) could affect initial

trial of the brand.

MODEL AND METHOD

There is little question that sales promotions effectively influence consumer behaviour. However, which sales promotion tools are generally most effective for achieving particular behavioural changes is not fully understood. In this study, five consumer promotion tools- coupons, discount, samples, bonus packs, and in-store display are investigated for their impact on consumer purchase behaviour. For example, purchasing a product they had never tried before (product trial). Items from Garretson and Burton (2003) study of consumer proneness towards sales promotion were used in the measurement of proneness to coupon, price discount, free sample, bonus pack, and in-store display, and the trialability behaviour of consumers to sales promotion was measured with items adapted from Gilbert and Jackaria (2002).

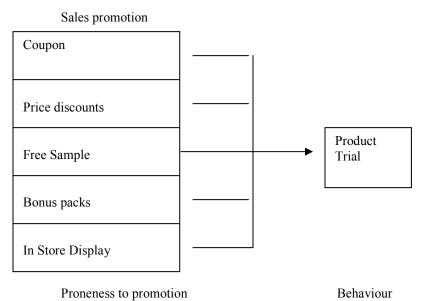
Figure 1 shows the research model. Questionnaire was used for the study. The population of the study consists of consumers in Kota Kinabalu, Sabah. The sample points were based upon on supermarket in Kota Kinabalu area. The survey instrument was a self-administered questionnaire that was distributed to the customers, either randomly or through personal networks. Some questionnaire was distribute personally to the existing customers of several supermarket located in the Kota Kinabalu area and administer face to face with respondents to ensure a high response rate, accurate sampling and providing necessary explanations (Oppenheim, 1992, p.103). Some respondents were given a self-administered questionnaire (to be answered at home) with a postage paid return envelope. A five point Likert scale, ranking from strongly disagree (1) to strongly agree (5) was used for the sales promotion and product trial scales. A total of 420 questionnaires were distributed around Kota Kinabalu and only 312 were returned, which represents a response rate of 74%.


Figure 1: Sales promotion and Consumer Buying Behaviour Framework

ANALYSIS

The data collected for this research was analyse by using Statistical Package for Social Sciences (SPSS) for windows. Multiple regression analysis was used to study the relationship between consumer trial behaviour with sales promotion. The regression assumptions with respect to autocorrelation (independent of residual), normality (residual is normally distributed), homoscedasticity of error terms, multicollinearlity and linearity of independent variables were verified before making any interpretation of the statistical result.

Before the regression results were accepted as valid, the degree of multicollinearity and its effect on the results was examined. The two-part process (condition indices and the decomposition of the coefficient variance) was employed

and comparisons made with the conclusions drawn from the variance inflation factor (VIF) and tolerance values. According to Hair *et al*. (1998) the condition indices and VIF not exceeding threshold values of 30 and 10 respectively are most commonly used. There is no high correlation between the independent variables in the regression as all condition indices and VIF fall below the threshold values. Lastly, there was a check for outliers (i.e. cases falling at the outer ranges of the distribution). A threshold of 3 standard deviations was used, which is appropriate for our sample size (Hair *et al*., 1998) to identify outliers. All observations outside this range (3σ) were considered outliers and were duly dropped from the regression

RESULTS

Reliability Analysis and Descriptive Statistics

Cronbach's alpha test was used to ensure the reliability of the variables. For sales promotional tools, the results indicate acceptable values: coupon (α=0.81), price discount (α= 0.86), free sample (α= 0.87), bonus pack (α=0.88), and in-store display (α= 0.87). The product trial value of Cronbach alpha for product trial is 0.81.

A total of 420 questionnaires were sent to consumers and 312 usable questionnaires were returned by respondents: 138 responses were received from supermarket around Kota Kinabalu, and 174 from personal networks. Analysis of gender revealed that 59.6% of respondents were female, whereas the male respondents consist of 40.4%. The majority of respondents' annual income level was below RM24, 000, which consist of 60.9% of respondents. Most of respondents were Chinese (51.6%). A greater percentage (62.8%) of respondents fall between 20-39 years old. And majority of respondents were non-university graduates (76.6%).

Mean score for all dimensions are as follows: coupon (2.99), price discount (3.67), free sample (3.08), bonus pack (3.28), in-store display (2.84), and product trial (3.22)

Table 1: Descriptive and Reliability Analysis Results

Variables	No. of Items	Mean	SD	Cronbach's Alpha Coefficient
Promotional tools				
Coupon	5	2.99	0.77	0.81
Price Discount	5	3.67	0.75	0.86
Free Sample	5	3.08	0.81	0.87
Bonus Pack	5	3.28	0.77	0.88
In-store Display	4	2.84	0.84	0.87
Product Trial	5	3.22	0.73	0.81

Sales Promotion as Predictor of Product Trial

The multiple regression analysis was employed to test the construct's relationships. Table 2 shows the results of the regression analysis used to determine the relationship between the promotional tools namely, coupon, price discount, free sample, bonus pack, and in-store display in one hand, and product trial in the other.

Table 2: Promotional Tools and Product Trial

Independent variables	Beta coefficients	t-value	p-value
Coupon	.023	0.401	.689
Price discount	.143	2.334	.020
Free sample	.218	3.483	.001
Bonus pack	.114	1.900	.058
In-store display	.234	4.322	.000

Note: R^2 = 0.294   F = 25.218   Sig. F = .000
Coupon, price discount, free sample, bonus pack, and in-store display contribute significantly (F = 25.22; p = .000) and predict approximately 30% of the variations in product trial. The 30% explanation is considered good for a

behavioural science research. The remaining 70% can be explained by other factors. Further examination of the results shows that price discount (t = 2.334; p = .020), free sample (t = 3.483; p = .001), bonus pack (t = 1.900; p = .058), and in-store display (t = 4.322; p = .000) are significantly associated with product trial. The results indicate that In-store display was the strongest predictor of product trial followed by free sample and price discount. Bonus pack was the weakest predictor of product trial.

There is no significant relationship at 5% significance level between coupon and product trial (t=0.401, p=0.689). Therefore, it is conclusive that coupon is not a strong determinant of product trial among the respondents.

DISCUSSION

The results of this study provide some useful information about the impact of five promotional tools on consumer buying behaviour (product trial). With respect to consumer proneness to sales promotions, the study found that in-store display promotion played the most significant role in shaping consumer product trial reaction. This finding can be supported by the view of Percy, Rossiter, and Elliott (2001), display promotions is one of the important parts of an integrated marketing communication programme that leads to better attention and consistent with consumer promotion and advertising, with the same look and feel, in order to increase recognition at the point of purchase (trial). From this finding, it is observable that in-store display is an effective promotional tool, and consumers are more sensitive to the product display. In other words, eye-catching, beautifully, and "easy to take" display in the store have the power to attract consumer to try a product that they have not tried before.

Free sample promotion was also found to significantly impact product trial. This finding is consistent with the definition reported in Pramataris, Vrechopoulos, and Doukidis (2001) that sampling is the activity of offering small quantities of product to consumers for free, in order for them to try it and potentially buy it. Therefore, it can be explained that free sample is one of the important factors influencing consumer buying behaviour, especially in the trial of a new product. However, the findings of the current research is in contrast with Gilbert and Jackaria (2002) and Scott (1976) findings, which found that free sample had no significant effect on consumer buying behaviour and sampling discouraged future purchasing.

From the statistical results, price discount is significant at 5% significance level. It means that price discount play a role in influencing consumer product trial behaviour. The findings are consistent with the views of Blackwell and his colleagues (2001) that price discount is strategically used in various industries to encourage product trial because price discount may reduce consumers' perceived risk associated with trying a new, less-familiar product for the first time. However, other authors have argued that some consumers will only respond to the bargain for a familiar brand (Ehrenberg and Hammond, 1994) and only the 50% discount can have significant effect on product trial (Scott, 1976).

Another sales promotional tool that have significant effect is bonus pack. Consistent with Lee (1963), which reported that bonus pack is used to increase consumer trial of a brand or product, this finding explains that more of the product included at no extra cost, can persuade consumers to buy a product for trial. Although, the significant effect of bonus pack to product trial is lower than other promotional tools such as in-store display, free sample, and price discount, bonus pack remains a useful marketing tool. The reasons why this happen can be explain by the view of Ong, Ho, and Tripp (1997). Ong, Ho, and Tripp stated that consumers might trust the price and quantity discount more than the bonus pack offer. In other words, consumers find it difficult sometimes to believe the bonus pack offered by the manufacturers. This happens because they believe that the price of product with bonus pack is slightly marked up by manufacturers in conjunction with bonus pack offerings. Thus, the only way for bonus pack promotion to encourage consumers product trial is to retain a few of the regular (non-bonus) packages on the shelves to let consumers compare between regular package and new bonus pack offer.

Contrary to what was expected and observed in Banks (2003), Schindler (1998), Blackwell, Miniard and Engel (2001), Robinson and Carmark (1997) where coupon had positive effect on product trial, coupon in this result does not seem to have significant effect on product trial behaviour. This result may have been caused by the fact that the respondents are not well familiar with the use of coupons. In fact in Malaysia, the use of coupons as a promotional strategy is not as common or popular as it is in the West. Marketers in Malaysia very seldom use coupons, resulting in the tool's unpopularity among Malaysian consumers.

Some of the reasons why consumers show very little interest in coupon are: first, the face value of a coupon is not

large. According to Percy, Rossiter, and Elliott (2001), generally, the face value of a coupon is not large because the retail price of the product is not high. Second, the period of redeeming coupon is short. According to Jackson (1996), normally, coupon is nearing its expiration date as a sales promotion technique. Percy, Rossiter, and Elliott stated that only the high value of the coupon and longer period available for redemption could attract consumers to redeem a coupon. Third, consumers in Kota Kinabalu are not familiar with coupon. Unfamiliarity with coupon by Kota Kinabalu consumers has resulted in the tool's failure to become an effective promotional tool to generate product trial. The finding corroborates Gilbert and Jackaria's (2002) findings that coupon didn't play a significant role in encouraging consumer to trial a product that they have not tried before.

IMPLICATIONS OF STUDY

Implications for Practitioners

The reported results have important implications for manufacturers and retailers involved in the elaboration and management of sales promotional tools. One of the major implications of this research is that manufacturers and retailers can increase their sales by offering the right promotional tools to attract customers to buy the product for their first trial. These results suggest that marketing managers need to carefully plan their promotional budgets and allocation of the budget over different forms of promotions. Promotions that emphasize in-store display, free sample, price discount, and bonus pack are likely to be more effective than coupon.

Second, the findings indicate that in-store display proneness has the strongest effect on product trial compared to other sales promotional tools. Attractive in-store display practices are necessary to gain the greatest sales from product trial and repurchase.

Third, bonus pack proneness as shown in the results significantly effect product trial, but the significance level is the lowest among other promotional tools. Thus, one way of improving the determinant power of bonus pack is to keep a regular pack along side with a bonus pack on the shelve, in order to enable consumers to make comparison. Such opportunity for a comparative observation will help to assure them that they are getting real value and no trick is being pulled at them. Consumers' confidence in bonus pack will be enhanced.

Fourth, the findings show that coupon have no significant effect to product trial, probably due to the smaller value of coupon, short period of redeeming the coupon, and unfamiliarity with coupon. Thus, it is suggested manufacturers and retailers use more coupon as their promotional tool, they should also extend the period of redeeming the coupon as well as create greater awareness of the benefits of coupons and how they could be redeemed. So that ignorant customers will be better informed about coupons and their uses.

Implications for Researchers

Understanding the impact of sales promotion on consumer buying behaviour. The Framework provides new insights into the understanding of sales promotional tools and its impact on trial. Why do consumers respond more to in-store display, free sample, price discount, and bonus pack than coupon that offers the same monetary incentive? One explanation may be that coupons require more skill and effort than buying a product on sale. For example keeping the coupon and redeeming it before expiring date, searching for a product that has coupon, matching coupons with brands, etc can be cumbersome and time consuming. In the other hand, price discount, free sample, bonus pack, and in-store display can provide shopping convenience benefit. Therefore, price discount, free sample, bonus pack, and in-store display promotion are more clearly signals the smart-shopping skills and values of the consumers. Researchers may wish to explore the reasons why coupon is not a product trial facilitator in Malaysia.

LIMITATIONS AND FUTURE RESEARCH

Although this study has provided an initial base for understanding sales promotional tools and their impact on product trial, there are few limitations to this study. First, product category or brand level was not included in the study. For example, a customer may be prone to a coupon promotion but they may not use the coupon to try all the different product. Moreover, various drivers (sales promotional tools) of trial may differ based on product type, for example consumer durables and services. Therefore, it is recommended to use different products and subjects in

future investigations in order to see if the observed effects can be generalized across product categories.

Second, unequal weighting of age and race of respondents is one of the limitations for this study. Most of the respondent in this study come from the age group between 20 to 39 years old. And almost 50% of them are Chinese. Unequally distribution of age and race could affect the result of this study. Therefore, the result probably cannot be used to generalize on the entire Kota Kinabalu consumers. It is suggested that sample distribution be improved in future research in this area.

There is still an urgent need to investigate the impact of promotional tools on product trial because research in this area is still inconclusive. Therefore, in spite of five specific types of deals (i.e., coupon, price discount, free sample, bonus pack, and in-store display) that was examined in this study, future research may choose to examine other types of sales promotions (e.g., contests, refund) on product trial.

In addition, studies that utilize data compiled by retailers that track buying and sales promotion participation habits across various types of deals could extend this study findings.

CONCLUSION

The findings of this study reveal that proneness to price discount, free sample, bonus pack, and in-store display positively impact product trial. The findings clearly indicate that sales promotion is an effective way to consummate product trial. It can also help to get a second chance at first time product buyers if promotion is continued.

Coupon is not a very popular promotional strategy in Kota Kinabalu. More awareness is needed in order for coupon to make any significant impact. Stores should display products attractively because in-store display promotion is an effective promotional tool in Kota Kinabalu. These issues are very important to practitioners and researchers interested in understanding the power of sales promotion as a viable marketing strategy.

ABSTRACT

Compelling evidence expounds that in the effort to improve business performance; customer satisfaction should be measured and managed. In fact, the new ISO 9000 revision requires firms to collect and act on their customer satisfaction data. Despite its undoubted importance, the attempt to understand what makes customers satisfied remains a difficult task, and this presents a key challenge and is a critical management issue today. Additionally, customer satisfaction findings were often criticised of being difficult to translate into managerial action. In light of these considerations, the present study aims to develop and formulate marketing strategies by utilising the Importance–Performance Analysis (IPA). IPA is an easy-to-use analytical technique that offers prescriptions for the management of customer satisfaction. However, it has been argued that there are two approaches in measuring importance of attributes: stated and derived. Therefore, our study sets out to compare the customer satisfaction ratings based on these two approaches. In contrast to the traditional IPA, our analysis was based on indicators that were established through rigorous assessment of exploratory factory analysis and purified via confirmatory factor analysis. Consumption behaviour of 400 direct sales channel customers in Malaysia was analysed. The results have important implications for future research directions and management practise.

INTRODUCTION

Accumulated research evidence has established that satisfaction may be a means to strategic ends; such as customer loyalty and customer retention, that directly affects company's profits (Bernhardt et al. 2000; Burnham et al. 2003; Jones and Sasser 1995; Shun et al. 2004; Zeithaml 2000). In view of this, it comes as no surprise that customer satisfaction has received much attention in the marketing literature and is the primary focus of our research endeavour. Whilst there has been resurgent interest in this research area, the critical issue of identifying the key factors that drive customer satisfaction has not been an easy task, specifically to the practitioners. Customer satisfaction findings particularly from the academic community have been criticised for being operationally irrelevant and difficult to be translated into managerial actions (Piercy 2002; Westbrook 1997, 2000; Woodruff 1993). In a similar voice, Petterson and Spreng (1997) assert that considerable research has focused on modelling the influence of perceived performance on satisfaction at the aggregate construct level; examining the effect of individual attribute performance on satisfaction judgement is more useful as it provides more diagnostic and actionable decisions for practising manager (Roszkowski 2003; Yuksel and Rimmington 1998). Accordingly, Westbrook (1997) suggests that to improve customer satisfaction measurement, research should address specific product or service features/dimensions and demonstrate how the key attributes are associated with overall customer satisfaction.

The purpose of a customer satisfaction study is not limited to identifying the key drivers of customer satisfaction and examining the actual satisfaction level experienced by customers, but also must extend to discovering the product or service attributes' strength and which require improvement (Ching 2003). Unquestionably, through this continuous improvement effort organisations may improve customer satisfaction evaluations and, ultimately, their bottom lines (Zeithaml 2000). Several scholars advocate that firms should embark on improvement actions on attributes that customers judge important though experienced lower satisfaction levels. In doing so, it helps the firms to make a more precise decision and deploy their scarce resources to achieve the optimum level of customer satisfaction. In an effort to identify and examine the attributes implicitly, Importance-Performance Analysis (hereafter IPA) has been recommended by several researchers as the most appropriate analytical technique (Johnson and Gustafsson 2000; Martilla and James 1977).

Although IPA could provide guidance for actionable plans in managing resources and infers priority area of improvement (Bacon 2003; Chu 2002), and has been suggested as the most applicable analytical tool to the practitioners, it is not without criticism. The critical issue often highlighted is that IPA is very sensitive to the importance measure employed. It was revealed that the items included in the final analysis and their interplay on the IPA grid depend on whether the customers' self stated judgement (stated importance) or some form of derived measurement was used (Chu 2002; Matzler et al. 2003). Typically, IPA uses direct ratings of importance known as 'stated importance' (e.g. importance rated on a 5 or 7-point scale anchored at 'not at all important' and 'extremely important'). On the other hand, others have strongly argued that indirect measures (derived importance) such as regression coefficients (beta values) (Bacon 2003; Chu 2002; Dolinsky 1991; Johnson and Gustafsson 2000) or correlation coefficients (Matzler et al. 2003) should be used to estimate the importance of attributes. Another shortcoming of IPA is that a slight change in an attribute's position in the grid might lead to a major change in its inferred priority and managerial actions direction (Bacon 2003).

In this sense, it is no surprise that issues such as how and why direct and derived methods may differ has long been debated and are major concern among several authors (Bacon 2003; Oh 2001; Matzler et al. 2003). Indeed, the validity of IPA as a managerial analytical tool has been frequently questioned (Bacon 2003; Oh 2001; Matzler et al. 2003). Recognising the aforementioned drawbacks and unresolved disagreements associated with the classical IPA, which primarily relies on the stated importance, clearly, it needs to be further validated, and modified or an alternative approach should be proposed.

RESEARCH OBJECTIVE

The primary purpose of our paper is sets out to compare the importance ratings and rankings of the two importance measurements (stated and derived approach), and demonstrate the critical differences when the key attributes are visually plotted on the IPA grids. Specifically, two derived importance methods will be utilised in this investigation, multiple regression (beta values) and correlation (coefficients). Importantly, we aim to illustrate visually how inferences made from the points plotted in the quadrant model across three methods employed for estimating attributes importance might yield different interpretations and strategies. Ultimately, an alternative approach to IPA, which is considered more rigorous is identified and proposed, which could be used by the direct sales practitioners with more confidence.

KEY CONTRIBUTIONS

While IPA has been frequently employed in previous studies, it is important to note that our empirical investigation is the first to utilise indicators (items) in the measures which have been purified through rigorous items analysis and subsequently by exploratory factor analysis (Churchill 1979). The measures were further refined by confirmatory factor analysis (Gerbing and Anderson 1988). Hence, this approach distinctively differentiates our IPA model from the prior studies. This approach is also in response to frequent calls made by prior researchers for IPA to use reliable measures and large samples in order to achieve consistent results (see, for example, Bacon 2003; Oh 2001; Roszkowski 2003).

Even though IPA has been used in various research contexts (notably education, leisure and tourism, health care sectors), to the best of our knowledge, this is the first time it has been used to examine customer satisfaction with the direct sales channel. What is more, we incorporate three interactive dimensions that constitute the direct sales marketing system (product, direct seller and direct selling company) in one IPA quadrant chart.

IMPORTANCE-PERFORMANCE ANALYSIS (IPA)

Business leaders have recognised the significance of business strategy to a firm's success across most industries (Robbins 2002). According to Barsky and Labagh (1992 p.32) "*despite the attention already given to customer satisfaction and strategic planning, each develop separately*". They further assert that strategic planning has not focused directly on customer satisfaction and similarly customer satisfaction does not have a strategic dimension. The practitioners require tools that could bring clarity to decision-making and problem solving. However, it appears that their efforts were bogged down by the lack of clear guidance on where to focus the attentions and efforts in allocating their limited resources. It has been widely acknowledged that IPA could fill this gap (Bacon 2003; Martilla and James 1977; Matzler et al. 2003). IPA has been a popular tool for providing richer insights into customer satisfaction and one that could afford suggestions to management for specific areas of improvement. More importantly, IPA is a practical and easy to-use tool for managers pressed for time.

Martilla and James (1977) first advocated this simple analytical technique, and over the years, many modifications and variations of IPA have emerged (Bacon 2003; Matzler et al. 2003). Traditionally, this analysis was based on perceived importance and attribute performance ratings evaluated by respondents, of which no statistical manipulation has been conducted. It has been consistently reported in previous research that customer satisfaction is a function of both consumer expectations related to importance attributes and perceived performance (e.g. Oliver 1980; Parasuraman et al. 1988). Interestingly, IPA is a simple yet useful tool that is capable of visually depicting the customer priorities (importance) against performance evaluation. The information derived from this analysis supports common managerial decisions. For example, IPA quadrant chart could yield a better understanding of customer satisfaction, identifying and prioritising critical area of improvements and provides guidance for action plans in allocating the firms' resources (Bacon 2003; Chu 2002; Lambert et al. 1997; Oh 2001).

IPA is a two-dimensional matrix (grid), which illustrate the perceived performance (satisfaction) along the x-axis and importance along y-axis. The grid is then subdivided into four quadrants by drawing a vertical line at the mean of the overall performance score and the mean of overall 'importance' displayed by the horizontal line (see Figure 1) and this yields four different strategies. The scaling and plotting of points in the quadrant model is crucial in IPA because the interpretation and inferences of results depends on them. It is worth noting that Martilla and James (1977) assert that the vertical and horizontal axes on the grid are a matter of judgement; the placement of these axes is considered a relative rather than absolute level of importance and performance. It was observed by Bacon (2003) that in some applications the point where the quadrant grid lines cross (cross-point) is positioned at the centre of the scale used (e.g. for 5-point scale the cross point is set at 3) and alternatively, in some cases the cross point is set at the centre of the data (mean value). However, recently Bacon (2003) provides empirical evidence that the data-centred quadrant predicts priorities for improvement better than scale-centred quadrant model.

Figure 1: Importance–Performance Analysis

Quadrant II High Importance/ Low performance **CONCENTRATE HERE**	Quadrant I High Importance/ High Performance **KEEP UP THE GOOD WORK**
Quadrant III Low Importance/ Low Performance **LOW PRIORITY**	Quadrant IV Low Importance / High Performance **POSSIBLE OVERKILL**

Source: Adapted from Mantilla and James (1977)

The position of a plot on the grid indicates the appropriate strategy to each product or service attribute investigated: '*Concentrate Here*', '*Keep Up the Good Work*', '*Possible Overkill*', and '*Low Priority*'. The following are the interpretations of zones in the quadrant chart:

Quadrant I: Keep Up the Good Work:
The attributes located in this zone according to customers are important and the performance is also satisfactory. This portion of the chart is also representing opportunities for gaining or maintaining competitive advantages (Barsky and Labagh 1992). This suggests that manager should maintain the superior evaluation and further exploit its competitive potential. Industry practitioners should perhaps continue to invest their effort and resources on such attributes.

Quadrant II: Concentrate Here:
The attributes that fall in this zone are considered importance by customers yet they do not perform well. According to Barsky and Labagh (1992), this zone is critical to gaining market share and this attribute can be shifted to 'critical strength' if resources can be reallocated from less important attributes. In essence, in order to enhance overall satisfaction, direct sales company should focus on these attributes and it is believed that if they are ignored, this might cause severe problems (Matzler et al. 2003).

Quadrant III: Low Priority:
The attributes located in this grid are deemed not important and the levels of performance are assessed being low. It suggests that although performance levels may be low, management should not give much priority to improving the attributes that fall into this quadrant as they are perceived to be not important, and obviously have less influenced on satisfaction evaluations.

Quadrant IV: Possible Overkill:
The attributes that fall into this grid are assessed by customers as not important yet they are reported to perform relatively well. This implies that managers should consider the present efforts on these attributes as being superfluous—this is a waste of resources. Therefore, if company needs to cut costs, these are the areas in which cuts could be made and should consider allocating some of these resources elsewhere (i.e., the 'concentrate here' quadrant).

STATED IMPORTANCE VERSUS DERIVED IMPORTANCE

Stated Importance:

The advantage of incorporating direct measure of performance from the customers' lens is that it provides insightful information as the level of importance of individual attributes is reported together with the perceived performance scores. For example, in one case study on student satisfaction, it was revealed that even though the quality of food service was frequently indicated as area of dissatisfaction for students. However, when requested to indicate the importance of this particular attribute to their overall educational experience, students rate food service relatively low (cf. Roszkowski 2003). This evidence strongly strengthens the argument of integrating the measurement of importance in customer satisfaction study. Furthermore, by measuring both performance and importance evaluation simultaneously, satisfaction gap scores can be derived by subtracting performance rating from importance rating. The gap is purported to imply how well the company or organisation performs relative to customers' importance evaluation on the specific attribute/dimension. The larger the gap, the poorer the performance as perceived by the customers (Bacon 2003; Roszkowski 2003).

Despite it is intuitively desirable to incorporate direct (self-stated) measure of importance in satisfaction measurement, several shortcomings have been observed. For example, it has been criticised for being a measure that reflects a social desirability and has been noted to be rated uniformly high as respondents might be unable to discriminate the degree of importance of the attributes examined, particularly when it involves a large range of attributes (Rao and Kelkar 1997). It was suspected that the self-stated approach did not adequately measured attributes based on customers satisfaction levels, rather were rated relative to each other (Matzler et al. 2003) and lacks of statistical significance testing of the scales used (Chu 2002; Duke and Mount 1996). Furthermore, the inclusion of importance ratings in the satisfaction research instrument will increase the burden for the respondent and several authors argue that stated importance might not be what actually drives consumer behaviour (Roszkowski 2003). What is more, relying on gap scores might pose some statistical problems (see, for example, Cronin and Taylor 1992).

Derived Importance:

Derived-importance approach applies the statistical mechanism such as regression and correlation analysis thus it is objective by avoiding human bias and it is possible to determine statistical significance of the attributes examined (Chu 2002). Furthermore, it requires only the performance ratings, thus inclusion of importance ratings are unnecessary (Chu 2002; Roszkowski 2003). The application of indirect techniques such as correlation analysis, assumed that the observed correlations reflect causal relationships. For example, significant correlation coefficient of individual attribute score against its dependent variable (i.e. overall performance/satisfaction) ratings indicates that the attribute is important. Whereas to compute the importance measures using multiple regression, the performance scores of each attribute is regressed against the overall performance ratings. The importance (i.e. magnitude of impact) of the attributes is determined by their corresponding standardised regression coefficients values (Hayes 1998; Mittal et al. 1999). A higher value implies that the specific attribute is an important predictor to overall performance/satisfaction.

Even though the 'derived importance' method is probably not distorted by the same biases as direct measures, it may be distorted when the assumptions underlying their statistical models are violated (Bacon 2003). However, Green et al. (1981) postulate that both types of measures of importance can predict product preferences. In addition, they provide evidence that the social desirability bias in direct measures of importance was not significant.

RESEARCH METHODOLOGY

The data utilised for the current investigation were collected in Malaysia by using self-administered questionnaires distributed via the 'drop off and collect' technique. The target population criteria for this study were adult consumers (over 16 years of age) who have purchased beauty or healthcare products from the direct

seller[1] within the twelve months prior to the data collection period (May – June 2002), and who live or work within the selected geographic locations; in this case three designated districts (Petaling, Kelang and the Federal Territory of Kuala Lumpur). A sample of 400 survey respondents was obtained based on a quota sampling technique. The ratio of men to women in the sample was set at 1:3, based on several empirical studies conducted in Malaysia and other countries suggesting women make up a significantly larger percentage of purchasers through the direct sales channel than men (Chen et al. 1998b; Endut 1999; Sargeant and Msweli 1999) and moreover the specific product categories under study (beauty care and healthcare) have more direct appeal to women. It should be noted that the current investigation is based on transaction specific approach rather than global (overall) experience.

Initially, 34 items were assessed individually to determine the relative importance and perceived performance respondents attached to these. Specifically, the informants were asked to rate the importance of the items (attributes) in fulfilling their satisfaction, while in the performance measurement respondents were requested to indicate their level of satisfaction with the items (attributes). Performance evaluation employed a 5-point satisfaction-dissatisfaction scale anchored with (1) "very dissatisfied", (2) "dissatisfied", (3) "neutral", (4) "satisfy" and (5) "very satisfied" and "not applicable". The importance rating is measured on a 5-point scale anchored with (1) "not at all important", (2) "not important", (3) "neutral (indifferent)", (4) "important", (5) "very important". The IPA grids are visually displayed in the form quadrant chart for each aspect of the direct sales marketing channel system. Table 1 exhibits the original pool of items used in the study before they are assess for unidimensionality, reliability and validity.

Table 1: Original Pool of Items

Product Satisfaction	Direct Seller Satisfaction	Company Satisfaction
1 Price of product	1 Knowledge of products and services	1 Reliable and trustworthy
2 Product performed as claimed	2 Capable and competent	2 Enquiry service responsiveness
3 Product is multifunctional	3 Being consistently courteous	3 Company's reputation
4 Product packaging	4 Following through on his/her promise	4 Sales campaigns / promotion
5 Effectiveness of product	5 Provide payment flexibility (instalment)	5 Corporate information / publicity
6 Product guarantee	6 Trustworthy	6 Handle complaints promptly
7 Product choice/variety	7 After sales service	7 Concern about customers
8 Product availability	8 Giving personal advice and attention	8 Company's popularity
9 Product information adequacy	9 Continuity of contact	9 Reasonable service charge
10 Product catalogue / brochure	10 Availability of direct seller	10 Product return/adjustment policy
11 Innovative and unique product	11 Maintain a professional appearance	
	12 Have customer interest at heart	
	13 Effectiveness of sales demonstration	

The pool of 34 items for performance measurement were assessed for item-total correlations and purified using exploratory factor analysis and subsequently validated using confirmatory factor analysis (structural equation modelling technique via AMOS 4 programme). The item-to-total correlation scores were in the range of 0.35 to 0.67, which signifies a reasonably good item performance. Exploratory factor analysis (hereafter, EFA) with Varimax rotation was first used to identify the underlying dimensions of the 34 items. Items that had high loadings (greater than 0.5) on a single factor and did not have cross-loadings greater than 0.3 (Rentz et al. 2002) on multiple factors were retained for further analysis. This initial purification exercise resulted in the deletion of ten items on the basis of failing to fulfil the criteria aforementioned. EFA on the remaining performance items was performed again and item-to-total correlations and Cronbach's alpha were computed for each factor extracted from this second run (Churchill 1991; Hair et al. 1998). All items loaded appropriately on the expected dimensions, which were: Product satisfaction, Direct seller satisfaction and Direct sales company satisfaction. The measures yielded a reliability coefficient (Cronbach's alpha) ranging from 0.80 to 0.88, which is greater than the recommended threshold of 0.70 (Nunnaly 1978).

It is widely recognised that more robust statistical tests such as confirmatory factor analysis (CFA) should be employed to confirm and verify the dimensions underlying the factors derived from EFA (Gerbing and Anderson 1988). Parallel to this suggestion, CFA was performed on the remaining 24 items using structural equation modelling and this resulted in a deletion of three more items. The estimation of the measurement model yielded respectable Goodness-of-Fit Index (0.91), Comparative Fit Index (0.93) and Incremental Fit Index (0.93) values. The Root Mean Square Residuals value of 0.03 confirmed a good fit, which exceeded the posited cut-off value (<0.05). The Root Mean Square Error of Approximation value of 0.06 was satisfactory. Overall, the results of the fit indices indicate that the measurement model adequately fits the data. Hence, it is

---

[1] Direct sellers, sometimes referred to as distributors or direct salespeople, are independent representatives of a direct selling company who have the right to sell and facilitate the distribution of the product to the end consumers

reasonable to believe that the measures utilised in our analysis have adequately met the unidimensionality, validity and reliability criteria applied[2].

Subsequently, the remaining 21 items were regressed against their respective criterion (dependent) variables, for instance indicators for product performance were regressed against product satisfaction (i.e. overall product performance) (Oliver 1997; Mittal et al. 1999). The same procedure applies to direct seller satisfaction and direct selling company satisfaction. Significant beta coefficient regression values derived for individual attributes and dimensions imply their 'importance'. In addition, correlation analysis was conducted on each attribute in order to delineate the relationships of these variables on overall performance, such as overall product performance (product satisfaction). Again a significant correlation coefficient would imply that the attribute is associated with satisfaction, thus, the attribute is important (Bacon 2003).

RESULTS AND DISCUSSIONS

The initial analysis performed was that of assessing the attributes performance and degree of importance and subsequently the satisfaction gaps were computed (performance mean values minus stated importance mean values). In order to illustrate the differences between self-stated and derived importance, the rankings of attributes were compared. We compare importance rating and ranking of individual attribute, which were assessed by self-stated approach and two derived importance assessment methods (multiple regression and correlation analysis). Table 2 displays the summarised results of the analysis. The results of the comparison of ratings, rankings and satisfaction gap across the three methods are organised according to the dimensions of direct sales channel.

Table 2: Summarised Results Of Performance Mean And Mean Differences, Stated Importance And Derived Importance

Items/ Factors	(A) Performance mean	(B) Stated importance Mean	C (A – B) Mean Differences	Derived Importance Regression Weight (Beta)	Correlation Coefficient
Product Satisfaction α = 0.80	3.77	4.12	-0.35	0.22	0.42

[2] Due to space constraint, these analysis procedures are not discussed

Product Dimension

Generally, the mean values of the product attributes (items) importance are higher compared to the mean values of performance. It is revealed that 'product effectiveness' was the most important attribute for product aspect (3.78). The largest gap between 'importance' and 'performance' mean values is product guarantee (0.58). This finding indicates that the direct sales company should improve on this attribute if they desire to increase customer satisfaction with their products.

With respect to importance rating by the stated importance method, the results indicate that item 1 (effectiveness of product) is the most important product attribute and was further supported by both derived methods, which are multiple regression and correlations. The critical differences are: Item 2 (product guarantee), item 3 (product information adequacy) and item 7 (product is multifunctional /multipurpose) were revealed to be insignificant predictors of product satisfaction when assessed by regression analysis. Interestingly, item 6 (innovative and unique product) is of low importance (6th of 7) when assessed by stated importance approach but in contrast was rated highly important when computed by regression (2nd of 7) and correlation method (3rd of 7).

Direct Seller Dimension

Table 2 suggests that the attributes of the direct seller dimension perceived by the customers fall short of the mean of 'importance' scores. It is unveiled that direct seller 'knowledge of products and services' was the most important attribute by self-stated method, and it was rated the highest in term of performance evaluation (3.81). Item 9 (have customer interest at heart) had the largest gap between 'importance' and 'performance' score (0.50). Therefore, this suggests that the direct sellers should improve on this attribute, perhaps by demonstrating their concerns and commitment to their customers.

Relying on the derived importance technique (multiple regression and correlations), item 13 (effectiveness of sales demonstration) was ranked the most important attribute of the direct seller satisfaction (1st of 8). Conversely, this specific item was ranked low in importance by stated importance approach (6th of 8). Item 12 (giving personal advice and attention) and item 15 (continuity of contact) were found to be insignificant driver of direct seller satisfaction by multiple regression analysis. It is worth noting that this item was ranked lowest in terms of importance by direct rating approach (8th of 8) and by correlation analysis (7th of 8).

Direct Sales Company Dimension

The results presented in Table 2 illustrate that the direct selling company dimension in terms of importance held in highest regard by the respondents is company's reputation (4.19) and ranked the highest in terms of performance (3.94). The largest gap between 'importance' and 'performance' score was item 18 (handle complaint promptly) (0.68). This implies that the direct selling organisations could improve their customer satisfaction by narrowing the gaps of this attribute if they are to retain their customers. Otherwise, their customers could switch to other companies, of which there are reported to be over 350 in the market currently (Ministry of Domestic Trades and Consumer Affairs of Malaysia Report, 2001).

Item 16 (company's reputation) had the highest rating of importance (1st of 6) by direct rating approach (stated); however it drops to 3rd and 6th rank by regression and correlation techniques respectively. Interestingly item 18 (handle complaints promptly) was ranked 3rd in term of importance by both stated and correlation methods, but was revealed to be insignificant by multiple regression. Additionally, item 20 (sales campaigns / promotion) was ranked relatively low in term of importance (5th of 6) by both stated and correlation methods and it was unveiled to be insignificant predictor of direct sales company satisfaction via multiple regression analysis. Interestingly, item 17 (concern about customers) was ranked the highest in terms of importance by both regression and correlation analysis and was ranked second by direct rating. The results imply that across three methods of assessing attributes importance, 'concern about customer' was rated relatively consistent.

In summary, the results demonstrate that the ratings and rankings of attributes (items) examined in this investigation were largely determined by the methods utilised to measure the attributes' importance.

Importance-Performance Analysis Results

Figure 2, 3 and 4 illustrate an importance – performance chart (grid), which was used to highlight and demonstrate clearly the four classifications of strategies. More importantly, in this section we will demonstrate that the outcome of an IPA is very sensitive to the assessment of attributes importance method employed. Figure

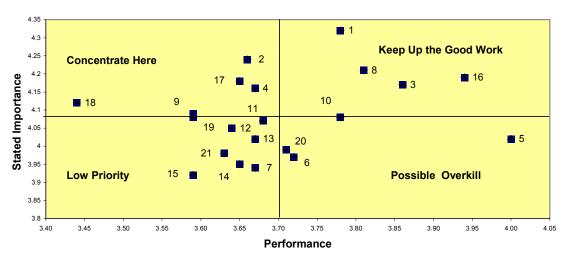
2 exhibits the IPA using the direct rating scale as a measure for attribute importance. The mean values for overall importance (4.09) and overall satisfaction (3.70) were used to split the axes, this produced four strategies. The summarised results of the IPA are illustrated in Table 3.


Figure 2: Quadrant Chart based on Stated Importance

           ** item appears in both stated and derived (correlation) approach   ****   item appear in stated, and derived (regression and correlation) importance approach

Quadrant 1: Keep Up the Good Work

In analysing the IPA matrix based on stated importance assessment approach as described in Figure 2, it implies that item 1 (effectiveness of product), 3 (product information adequacy), 8 (Knowledge of products & services) and 16 (Company's reputation) are the key drivers of customer satisfaction with the direct sales channel and the industry's practitioners must maintain to 'Keep Up the Good Work'. Compared to IPA based on regression analysis as illustrated in Figure 3, item 1 (effectiveness of product), 6 (innovative and unique product) and 8 (knowledge of products & services) are the key drivers of customer satisfaction with the direct sales channel. While IPA based on assessment of product importance by correlation analysis shows that item 1 (effectiveness of product), 8 (knowledge of products & services) and 10 (Being consistently courteous) are the key drivers of customer satisfaction with the direct sales channel. Apparently, only two items, which are 1 (effectiveness of product) and 8 (knowledge of products & services) fall into the same quadrant (Keep up the Good Work) across three models. The critical difference is that item 3 (product information adequacy) which is identified as a key driver of customer satisfaction in stated importance model, now falls in 'Possible Overkill' zone in correlation analysis method and conversely it was found to be an insignificant driver of customer satisfaction with the direct sales product when the attribute importance was evaluated by regression analysis.

Quadrant II: Concentrate Here

It is noteworthy to mention that only Item 4 (product performed as claimed) and Item 17 (concern about customers) fall into Quadrant II across three methods of attribute importance evaluation. Interestingly, item 2 (product guarantee) was categorised as prioritised area that need improvement as satisfaction is low and importance is high in direct importance rating, it was unveiled to be not a significant driver of customer satisfaction with the direct sales channel by regression analysis. However, 'product guarantee' falls into the low priority zone when importance rating was assessed by correlation analysis. In addition, item 18 (handle complaints promptly) was classified as high priority area for improvement by both stated importance and correlation analysis; however, it was not a significant predictor of customer satisfaction with the direct sales company.

Quadrant III: Low Priority

It appears that only item 21 (corporate information/publicity) falls into the same zone across all the three methods. Item 13 (effectiveness of sales demonstration), which is considered a low priority area by stated importance; on the contrary, it becomes a high-priority area when assessment of importance was conducted by regression and correlation analysis. Similarly, item 14 (maintaining a professional appearance) categories as low priority area by both stated importance and regression methods; on the contrary, it becomes a high priority area for improvement by correlation analysis.

Quadrant IV: Possible Overkill

Item 5 (product catalogue) was found to be located in the same zone across the three quadrant charts and item 20 (sales campaigns / promotion) which was classified as 'possible overkill' by direct rating and correlation analysis, found to be an insignificant driver of customer satisfaction with the direct sales company. It is worth noting that item 10 (being consistently courteous) which is considered as attribute of performance 'overkill' by both direct rating and regression analysis, surprisingly, it becomes a key driver of customer satisfaction when assessed its importance via correlation method.

In summary, the results presented by this study demonstrate that the points plotted in the three quadrant charts were inconsistent and the differences were probably influenced by the measurement of importance employed.

The Final Importance–Performance Analysis Model

Figure 5 portrays the resulting items which fall in the same zone when three methods were employed to assess attributes importance. The results demonstrate that Item 1 (effectiveness of product) and Item 8 (knowledge of products & services) fall in the 'Keep Up the Good Work' grid. This suggests that they are the key drivers of customer satisfaction with the direct sales channel−in other words these two attributes could be viewed as sources of significant competitive advantage. Item 4 (product performed as claimed) and item 17 (concern about customers) are located in 'Concentrate Here' zone. This indicates that these areas demand immediate actions. By prioritising improvement on these areas, practitioners might enhance overall customer satisfaction. However, if they are ignored this might pose a serious threat to the direct sales firms. Item 21 (corporate information / publicity) was revealed to be a 'Low Priority' area, hence it is not necessary for the management to focus additional effort here. Finally, it was identified that resources committed to item 5 (product catalogue), which is deemed a 'Possible Overkill' should be channelled to attributes located in the 'Concentrate Here' zone.

In essence, the combination of the three methods could identify the key drivers of customer satisfaction with the direct sales channel and areas need improvements with more confident rather than just relying on the self-stated approach. In addition, since the results of the analysis are based on attribute level, they could generate precise actions plans to the direct sales practitioners.

Quadrant II High Importance/ Low performance **CONCENTRATE HERE** **Item 4 (Product performed as claimed)** **Item 17 (Concern about customers)**	**Quadrant I** High Importance/ High Performance **KEEP UP THE GOOD WORK** **Item 1 (Effectiveness of product)** **Item 8 (Knowledge of products &services)**
Quadrant III Low Importance/ Low Performance **LOW PRIORITY** **Item 21 (Corporate information/ publicity)**	**Quadrant IV** Low Importance / High Performance **POSSIBLE OVERKILL** **Item 5 (Product catalogue)**

Figure 5: The Final Importance-Performance Analysis Model

CONCLUSIONS

The results for the comparison of ratings and rankings across the three methods clearly demonstrate the significant influence of the methods of determining the attributes importance. Only item 1 (effectiveness of product) was ranked as the most important attribute for product satisfaction across all the three methods. Surprisingly, after rigorous measurements assessment, our investigation revealed that seven items (2, 3, 7, 11, 15, 18 and 20) were not significant drivers of customer satisfaction (see Table 2). We suspect that methodological factors such as social desirability bias and extreme response tendencies due to lack of 'cognitive sophistication' (Rao and Kelkar 1997, p. 81) resulted in uniformly high ratings in self-stated importance ratings (see Table 2). Thus in this sense, we recommend that future research to cross-validates the direct rating for assessing the attributes importance with more rigorous statistical analysis techniques such as multiple regressions and correlation analysis in the order to achieve more accurate measurement of importance.

Alternatively, a satisfaction gap scores can be interpreted as an area of potential improvement and requires immediate attention, which is equivalent to the 'Concentrate Here' strategy in the quadrant chart. Apparently, this indicates that the direct sellers or the direct selling companies should give their priority to make improvements in this area. By improving the 'importance' attributes that fall short of 'performance' judgement by the customers, the company could yield the desired outcomes and prevent money being spent on improving unimportant attributes. In short, the findings could provide clear guidelines for direct sellers or companies in allocating and aligning internal resources and effort in order to maximise customer satisfaction and perhaps subsequently their retention. Our results, which are illustrated in Table 2, revealed that item 2 (product guarantee) had the largest gap (0.58) falls appropriately in the 'Concentrate Here' zone in the quadrant charts based on stated importance (see Figure 2). In contrast, it was located in 'Low Priority' zone in the quadrant chart based on correlation analysis (see Figure 4). Surprisingly, this item was not a significant driver of product satisfaction. The largest gap for direct seller (have customer interest at heart) (0.50) was appropriately located in the 'Concentrate Here' zone for both self-stated and correlation analysis methods for determining attributes importance but conversely this particular attribute fall in the 'Low Priority' zone in the quadrant model based on regression method. It should be noted that the largest gap for the direct sales company dimension (handle complaint promptly) (0.68) was located correctly in the 'Concentrate Here' zone for both self-stated and correlations analysis approaches but this specific item was not a significant driver of customer satisfaction with the company. The findings were perplexing but relatively consistent across the three methods employed to assess attributes importance. Nevertheless, this analysis must be used prudently and the results should be interpreted with caution.

Generally, the results of IPA presented by the current investigation reflect that the matrix is sensitive to the importance measure used. These empirical findings further support the similar evidence drawn by previous researchers (see, for example, Matzler et al. 2003). Clearly, this research has demonstrated that classical IPA

could be misleading even when valid and reliable measures were used. Only one or two attributes fall into the same zone when the attributes importance was assessed across three methods. Thus, we strongly encourage users not only to employ direct importance ratings but to cross-validate it with other methods of assessing the attributes' importance such as regression and correlation analysis as presented by our final IPA model (see Figure 5). In addition, we suggest researchers and practitioners employ valid and reliable measures when conducting IPA, as our results demonstrate that several items fall into the same zone even though different methods of assessing the attributes' importance were utilised and has been confirmed by previous researchers (see, for example, Bacon 2003 and Matzler et al. 2003). IPA approach as suggested by our study may not be a simple analytical technique, when compared to its classical version, however it is still considered applicable and relevant to the practising manager. The crucial question is how valid is IPA as a tool that yields prescriptions for courses of action that a company can pursue in the aim to manage customer satisfaction. In our view, if IPA is to be employed confidently, the trade-off between simplicity (which not producing consistent results) and difficulty of employing more rigorous approach as suggested by our work (which more likely generate valid results) is certainly worth strong consideration.

It should be noted that a limitation of this study is that the ratings of the attributes' performance and importance might be influenced by respondents' demographic backgrounds and experiences. It is reasonable to speculate that as a consequence, IPA yielded mixed results where clear and logical trends difficult to be recognised. In this regards this could offer a fruitful future research direction, IPA need to be closely examined which would demand a theoretical explanation. Specifically, future research should develop IPA models based on different customer segments. It is possible and reasonable to suspect that demographic segments such as gender and age or level of customer experience could produce significantly different results. Perhaps, precise area of improvement could be determined and immediate managerial plans and actions might be effectively tailored to these customer segments.

ABSTRACT

The purpose of this paper is to examine the effect of consumers' ethnocentrism, materialism attitude, and prestige sensitivity on purchase intention of Malaysian made products. The conceptual model, based on Fishbein and Ajzen's (1975) theory of attitude and behavioral intentions model of reasoned action, was developed to generate the hypotheses. The findings of the study indicated that consumers' ethnocentrism was positively related to purchase intention of Malaysian-made product. On the other hand, as we expected, materialism attitude and prestige sensitivity consumers were unlikely to purchase Malaysian-made products. This paper considers the connection between marketing, the consumer society and the perspectives of retailing and merchandising. Conclusion drawn from the current study's findings and their implications are discussed in the context of both managerial perspectives and future research.

INTRODUCTION

The globalization of business has resulted in increased competition among domestic and multinational firms in domestic and foreign markets (Netemeyer, Durvasula, Lichtenstein, 1991; Suh and Kwon, 2002). The increased of global competitions have giving consumers more buying choice at the very competitive prices (Abdul Razak, Safiek, Md Nor, 2002). The positive improvement of political and economic pace provides much potential for foreign marketers to invest in the potential market around the globe. For example, the progressive economic development in Malaysia has attracted many global firms to operate in its markets. To penetrate successfully in Malaysian market, marketers must understand the consumers' varying needs and preferences toward domestic and imported products.

The globalization of markets also has lead researchers and business practitioners to identify factors that influence consumer attitudes and behavior towards Malaysian-made products. For that reason, research on consumer ethnocentrism, materialism attitude, and prestige sensitivity may be an important step to understand the way in which individual and organizational consumers compare domestic versus imported products, as well as the reasons that lead them to develop patriotic prejudices against import (Martinez, Zapata, & Garcia, 2000).

The above discussion leads the current study to address the following question: How can marketers effectively position their product to influence Malaysian consumers' purchase intention toward domestic product? Does consumer ethnocentrism play an important role in decision-making when product of interest is an important source of jobs and income for domestic economy? Does materialism attitude have strong effect on consumer purchase intention of imported products, due to it material possession and outlook? Will consumers perceive better quality and prestige sensitivity of imported products part of the reasons for them to buy more imported products versus domestic products?

Although previous research identified consumer purchase intention on imported products, only few researchers have examined consumers' ethnocentrism variables in relation to Malaysian consumers. As well, while previous research is certainly valuable, one cannot help but notice the absence of studies investigating the effect of material attitude and prestige sensitivity on Malaysian consumers purchase intention. In the current study, we use the Fishbein and Ajzen's (1975) theory of attitude and behavioral intentions model of reasoned action as a basis for providing a better understanding of the interrelationship among the listed variables.
The current study was interested in examining consumer ethnocentrism, materialistic attitude, and prestige sensitivity, and their effect on consumer purchase intention of Malaysian-made products. This study is to improve our understanding of why certain segments of consumer prefer domestic products while others do not care about the distinction between domestic and imported product categories.

It is hoped that the findings of this study would add to the existing empirical research and knowledge in the local and international context to both academicians and practitioners. Further we anticipated that the finding of the

current study would help either local or international business practitioners and marketing and retail managers to position their products in the Malaysian market by using appropriate marketing mix strategies.

LITERATURE REVIEW

We reviewing relevant literature based on the theoretical background provided in the conceptual framework section. Much emphasis will be given to the findings of the studies rather than the methodology adopted. The literature review is relevant to the current study deals with consumers' ethnocentrism, materialistic attitude, prestige sensitivity, and purchase intentions.

Several theoretical perspectives in term of consumers' purchase intention have been discussed in consumer behavior literature. In the current study, we examine the variable of consumer ethnocentrism, materialism attitudes, prestige sensitivity, and purchase intention through the perspective of Fishbein and Ajzen's (1975) theory of attitude and behavioral intentions model of reasoned action. This theory describe conceptual framework to establish the context of the current study subject.

According to Fishbein and Ajzen (1975), an attitude is defined as beliefs the person holds about something, whereas behavioral intention is the predictor of person behavior. Reasoned action involve the implications of individual deliberate action before decide to engage in a given behavior and consider all the advantages as well as disadvantages before reflect on their attitudes.

Fishbein and Ajzen's (1975) theory does specify that a particular attitude associate with a particular behavior, which suggest that observers infer from a consumer's behavior dispositions lead observers to make either favorable or unfavorable attitudes about him or her. The Fishbein and Ajzen's (1975) theory have been used to explain relationships between attitudes, intentions, and behavior (Vaidyanatahan, Aggarwal, Stem, Muehling, & Umesh, 2000). On the basis of the above explanation, we believe that this theory has brought new ideas to the study of consumers' ethnocentrism, materialism attitude, and prestige sensitivity and provides some explanations for purchase intention.

Derived from the Fishbein and Ajzen's (1975) theory, we imply that consumer ethnocentrism reflects theirs belief on the virtue of purchasing domestic products. Consumer attitude on ethnocentrism is need as well in differentiating consumer groups who prefer domestic product to imported product (Huddleston, Good, & Stoel, 2001). The theoretical argument described above is based on the assumption that consumers are expected to favor domestic product and to reject imported products based on the belief that buying imported products is unpatriotic and would damage national economic.

Based on the Fishbein and Ajzen's (1975) theory, we could explain that consumers' materialism attitudes toward accumulation of possession is influenced by their attitude and behavior to express a distinct self-identity through the variation of economic level and social status. The literature on materialism provides a framework, which helps to understand the meaning that consumers attach to worldly possessions may impact the differences in consumer attitudes, thereby creating an inconsistency between their materialistic attitude and purchase intention. Applying theory of attitude and behavioral intention to materialism, we conceive that materialism people define possessions as the center of theirs life and their happiness depends on the possessions of goods rather than social interaction (Browne and Kaldenberg, 1997).

Consumers' belief constitutes reasons for action and makes a coordinated contribution to determine the action that result from their action and belief to own prestigious product (McGowan and Sternquist, 1998). Based on Fishbein and Ajzen's (1975) theory, we imply that consumers attitude inspire them to have a prestigious lifestyles that represents distinction in an area related to one's self image. This is to the assumption that consumers' attitude and behavior lead observers to make favorable image on their prestige life. Accordingly Fishbein and Ajzen's (1975) theory support the notion that prestige sensitivity consumers need to communicate their prestigious self-identity by frequently purchase certain products and merchandise that show the exclusivity of their social status and symbolic consumption qualities to various others. Thus, we relate that intention provides a link between consumers' reaction to the products purchase and their acquisition of the prestigious products.

Lying on Fishbein and Ajzen's (1975) theory, we generate that consumers' purchase intention serves as the mediator between their attitude and their actual purchase behavior. Purchase intention is a surrogate measure of future behavior that has been a well-established phenomenon in the literature (Fishnbein and Ajzen, 1975). For example, in the study related to purchase intention, the attitude and behavioral intention relation was found to be consistent as information processed is available about the consumers' attitude towards products (Whitlar,

Geurts, & Swenson, 1993). This relation has received widespread empirical support in consumer behavior research, which posits that an attitude is subjective norms that influence intentions. Although normally a direct positive relationship exists between attitudes and behavioral intentions, we expect it is also commonplace to come across counterexamples in everyday shopping behavior where consumers' attitudes have varied their purchase intention.

Consumer Ethnocentrism

A measure of ethnocentrism makes sense in a study on consumers' purchase intention, where the appropriateness and morality of purchase imported, rather than domestically, may be in question. Shimp and Sharma (1987) introduced the phrase "consumer ethnocentric tendencies" to represent beliefs held by American consumers about the appropriateness, indeed morality of purchasing foreign-made product (p.280). Consumer ethnocentrism also refers to the phenomenon of consumer preference for domestic products but prejudice against imports due to nationalism and patriotism (Levine and Campbell, 1974; Caruana; 1996; Martinez et al., 2000). Consumer ethnocentrism also focuses on immorality of purchasing foreign made due to the belief that it is unpatriotic and detrimental to the economy, and results in loss of jobs in local industries (Shimp and Sharma, 1987; Kucukemiroglu, 1999; Klein and Ettenson, 1999).

Shimp and Sharma (1987) developed a 17-item scale called CETSCALE (Consumer Ethnocentric Tendencies Scale) to assess consumers' ethnocentric tendencies. Although CETSCALE originally introduced in the context of American consumers, researchers in a limited but growing number of countries have tested the ethnocentric tendencies of consumers. It has been expected to show similar effects across national boundaries. Studies have consistently found that the more ethnocentric a nation is, the less favorable their attitudes and the less likely they will hold purchase intentions towards foreign products (Han, 1988; Durvasula, Andrews, & Netemeyer, 1992; Flynn and Goldsmith, 1993; and Herche, 1994). The concept of ethnocentrism is a potentially valuable explanation of why consumers often develop negative orientations towards foreign-made products (Watson and Wright, 2000). This negative orientation towards purchase intentions of foreign products has been found with consumers in France and Japan (Netemeyer et al., 1991).

Levels of ethnocentrism refer to differences between micro-ethnic, regional, and macro-ethnic groups (Caruana, 1996). The more importance a person places on whether a product is made in his/her home country, the higher the ethnocentric tendency. Highly ethnocentric people take pride in their own values, symbols, and people, and hold in contempt the objects and values of other groups (Preiswerk and Perrot, 1978; Netemeyer et al., 1991). They are most prone to biased judgment by being more inclined to adopt the positive aspects of domestic products and to discount the virtues of foreign-made products (Kasper, 1999). Highly ethnocentrism consumers feel that they should buy more local products, whereas low ethnocentric consumer feel that they do not exhibit such concerns and tend to assess imported products based on their own merits (Kaynak and Kara, 2002). By using the CETSCALE, we could verify that consumers exhibit different levels of ethnocentrism, based on the strength, intensity, and magnitude that vary from country to country (Huddleston and Good, 1995).

Materialism Attitude

A growing body of research suggests that people engage in consumption behaviors indicate to others that they are successful in achieving their materialism possessions and quality of ownership (Richin and Rudmin, 1994; Belk, 1995; Ryan and Dziurawiec, 2001). In general, the concept of materialism suggests that possessions and money is route to personal happiness and social progress (Moschis, 1981).

Richins and Rudmin (1994) describes materialism in terms of its role in consumer culture as "the idea that goods are a means to happiness and life satisfaction is not achieved by religious contemplation or social interaction, or simple life, but by possession and interaction with goods. Materialism is also defined as a value held by an individual, who embodies the importance one attaches to material possessions and their acquisition as a necessary or desirable form of conduct to reach desired end states including happiness (Belk, 1995; Richins and Dawson, 1992). Materialist people perceive that gain pleasure from acquisition of wealth and possessions of material goods is the triumph and as means of providing great satisfaction in their lives (Ryan and Dziurawiec, 2001).

In essence, materialism is a value orientation that has implications for people's desires, decisions, and psychological well being of social behavior. Materialism incorporates the importance of certain end states and the belief that possessions are the means to achieve these end states (Ryan and Dziurawiec, 2001). Belk (1984) argues that materialism can be thought of as a cluster of related traits, attitudes, and values focusing on

possessions and guiding the selection of products. Materialistic individuals are prone to be acquisitive, to have positive effects related to acquisition, and to place high priorities on ownership (Browne and Kaldenberg, 1997). The possessiveness, lavishness, and envies represent materialism in that they express a person's relationship to materially object by defining status and stylistic intelligence in the function of possessions assemblage. These attitude affluence consumers to accumulate their material possessions as a consequence of wealth, serve as a live information system to signal to others the owner's self-image, rank, values, invoices thought, beliefs, desires, intentions, and sensory experience (Richin and Rudmin, 1994; Browne and Kaldenberg, 1997).

As motivation, materialism has a status component that reflects the intended and actual use of material objects as a means of social recognition and to symbolize one's personal success (Richins and Dawson, 1992). The component of materialism involves status and purchases high quality and high price products to distinguish themselves from others. Undeniably, materialism is a common value orientation among people in industrialized capitalistic cultures. The apparent indicator of people in industrialized capitalistic cultures involves a desire to own expensive product; as a means for life comfort, luxury achievement, and financial success (Dittmar, 1992). When a culture places a strong emphasis on individual economic accomplishments, people tend to develop extrinsic aspirations involving assets and acquisitions, and success with social recognition (Prendergast and Wong, 2003). Acquisition of possessions, and luxury consumption are activities taking place in a process of impressions creation of material identity (Marcoux, Filiatrault, & Cheron, 1997).

Prestige Sensitivity

Only few marketing researchers have empirically examined prestige shopping behavior and the factors that lead consumers to perceive specific products categories as prestigious item. Although Lichtenstein, Ridgway, and Netemeyer (1993) use prestige sensitivity as indication for price cue, their study does not address the extensive myriad of other cues within shopping environments and purchasing behavior. In the current study, prestige sensitivity is expected to relate more with socially visible products and behaviors that consumers might regard as indicative of prestige or congruent with their own self-image.

Prestige sensitivity is defined as favorable perceptions of the price cue based on feelings of prominence and status that higher prices signal to other people about the purchaser (Lichtensein et al., 1993). Prestige has always been designated as constituting a basic symbol of one's social standing of status. An important class of symbols involves association with a prestigious group that represents excellence or distinction in an area related to one's self image (Dawson, 1988). Within the context of symbolic consumption, individuals with a strong need for prestige seek to purchase products for their symbolic qualities because such products represent a means to communicate one's actual or desired for social status.

As previously mentioned, prestige sensitivity views as the propensity to make attributions made by other consumers on the basis of the price level. Prestigious consumers are more likely to pay higher prices for merchandise that they valued to be prestigious (McGowen and Sternquist, 1998). Lichtenstein et al. (1993) state that higher price can make a product more attractive because the price is taken as an indicator of the prestige value of the products. It has been suggested that prestige sensitivity is related to socially visible behaviors, whereas a price/quality schema is influenced by cues that reinforce the validity of using price to imply quality (McGowen and Strenquist, 1998). Braun and Wicklund (1989) mentioned that as price conscious as consumers have become, they are willing to pay more for products in which they have an ego investment on the products. Consumers pay more when they feel that high-priced products will signal high quality, and convey prestige to others (Jin and Sternquist, 2003). In Japan and the United States people use high price as a proxy for quality and an indication of prestige (McGowan and Sternqusit, 1998).

Prestige sensitivity is expected to present in more socially visible behaviors, such as shopping for expensive, stylish, elegant, and luxury types of products. Consumers expect to find high quality products and merchandise in more prestigious stores (Heisey, 1990).
In the study of prestigious clothing, Deeter-Schmelz, Moore, & Goebel (2000) defined prestige preference as an individual's preference for shopping in clothing store where the combination of patron status, store types and atmosphere, merchandise price, quality, branding, and fashion are combine to create a particular prestige level. Besides price and quality, brand name also reported to be very important key indicator with regards to prestige preference (Dawson, 1988). Individual tend to relate brand symbols to self-concepts; with preferences for high prestige brands that reinforce their own actual or desired prestigious self-image, and communicate this self-image to others.

Purchase Intention

Earlier research has shown that consumers who report intentions to purchase a product possess higher actual buying rates than consumers who report that they have no intention of buying (Berkman and Gilson, 1986). While it is accepted that purchases intention does not equate to actual purchase behavior it has been demonstrated that measures of purchase intention do possess predictive usefulness (Jamieson and Frank, 1989). Such utility is likely to be interest to producers, manufacturers, marketers, and retailers.

According to Whitlark et al. (1993) purchase intention means that a purchase probability associated with an intention category at the percentage of individuals that will actually buy product. Purchase intention measures have been used frequently to identify buying livelihoods for products within defined time periods (Whitlark et al., 1993). Purchase intention surveys give good forecast for marketing the new products (Jamieson and Frank, 1989). Percentage of buyers for a particular product can be estimated by asking consumers to indicate their likelihood to purchase using a multi-category purchase intention scale. Measuring this purchase likelihood, Whitlark et al. (1993) found that seventy five percent of those consumers who stated a purchase intention did purchase within three months.

Understanding that consumer belief about the products can be a significant factor influencing consumers purchase intention, thus a sales and purchase forecast often plays an important role in marketing strategy. It provides a basis for estimating profits associated with implementing a particular marketing strategy. A common forecasting method used by businesses to forecast the sales of a new product is to ask potential customer the likelihood of purchasing the product that is being investigated (Jamieson and Frank, 1989).

Consumer responses to probability statements like "probably will buy" or definitely will buy are often used by businesses to forecast sales of new or modified products. While this technique is widely used, there is little published research on the relationship between an individual's purchase intentions and actual purchase behavior. It would be useful to know what percent of those who say they are in the "probably will buy" group actually buy (Whitlark et al., 1993). An evaluation of consumers' product perceptions and characterization is important to assess consumers' demand.

RESEARCH METHODOLOGY

Sampling And Data Collection

In an attempt to increase our understanding of consumer ethnocentrism, materialistic attitude, and prestige sensitivity on purchase intention of Malaysian-made products, one-product category was selected for empirical testing. We choose furniture as our product category in the current study. A simple random sample is used as a method of data collection. The samples were drawn from faculty staff in one of the universities in Malaysia. The questionnaires were attached with self-adhesive envelope. Altogether 800 copies of questionnaires were mailed to respondents between 22 to 24 December 2003. Though the samples cannot be viewed as nationally representative, they do constitute comparable populations who purchase Malaysian-made products. The samples different in terms of age, level of education, and work position that are expected to have variation in their feelings of ethnocentrism, materialism attitude, and prestige sensitivity on purchase intention of Malaysian-made products.

Instrument and Measurement

A self-report questionnaire was developed based on past research in order to collect information to test the hypotheses. The questionnaires contained 50 items that included measurement of ethnocentrism, materialism attitude, prestige sensitivity, and purchase intention scales. The surveys were taken from previously developed scales and modified when necessary. The first section of the mailed questionnaire included questions about ethnocentrism, materialism attitude, prestige sensitivity, and purchase intention. The last section included demographic and socioeconomic questions, which are used to interpret the responses on other questions. The mailed questionnaire technique is argued to be efficient when the researcher knows exactly what is expected from the questionnaire, and knows how to measure the variables (Sekaran, 1992). It is also a good technique when the target respondents are knowledge enough to understand the questions on their own.

Pilot Study

The questions have to be finalized before they are distributed because clarification and changes to the questions are impractical. Since the surveys are taken from previously developed scales, we modified it when necessary and pilot tested the revised version. The pilot test sample included thirty respondent and reliabilities is accepted for all the scales. The results from this pilot study provided us with the research direction. All items in the questionnaire were randomly mixed to prevent a reference bias. Reliability for the small pilot sample size was .52 to .86 (Table 1). Corresponding coefficient alpha estimates for ethnocentrism, prestige sensitivity, materialism attitude, and purchase intention were .86, .70, .52, and .63, respectively (Table 1). These results were considered satisfactory (Nunnally, 1978). Since reliabilities were still not acceptable for some sales we further revised the wording for the problematic items before the final questionnaires were sent to the respondents.

Table 1: Comparison Between the Previous Scale Reliabilities and the Pilot Test

Items	Previous scale	Pilot test
Consumer ethnocentrism	.91 to .96	.86
Materialistic attitude	.61 to .84	.70
Prestige sensitivity	.78 to .98	.52
Purchase intention	NA	.63

Consumer Ethnocentrism

The current study used Shimp and Sharma's (1987) consumer ethnocentrism (CETSCALE) to measure consumers' ethnocentrism as a basis for identifying consumer attitude, characterization, and market segmentation. This scale has been tested and found to be reliable and valid in the USA, France, Japan, West Germany (Netemeyer et al., 1991), Russia (Durvasula et al., 1992), Korea (Shimp, Sharma, & Shin, 1995), and Poland (Huddleston and Good, 1995). Coefficient alpha ranged from 0.91 to 0.96 in all of the above studies, giving evidence of internal consistency. The Cronbach's alpha for pilot test was .86 (Table 1). The scale proved to be reliable and provided for contingent and discriminant validity in virtually all samples to which it was administered. The 17-items of CETSCALE measure the tendency of consumers' attitude towards foreign and domestic products. Respondents were asked to indicate their agreement with each of 17 statements, ranging from (1 = strongly disagree to 5 = strongly agree).

Materialistic Attitude

The instrument for measuring materialistic attitude was developed based on past research (Moschis, 1981; Tashchian, Slama, & Tashchian, 1984; Richins and Dawson, 1992). The coefficient alpha of the scale on previous study ranged from .61 to .84. Materialistic attitude was measured with nine different items. Materialism scale measure the individual's material symbols and reflections of identity in terms of social-material status. The reliability of the scale for the pilot test, computed with Cronbach's alpha was .70 (Table 1). Scorings accomplished with a five-point Likert format (1 = strongly disagree to 5 = strongly agree).

Prestige Sensitivity

Lichtenstein et al., (1993) price-based prestige sensitivity and product-quality scale are used to measure prestige sensitivity. Lichtenstein et al. (1993) reported the coefficient alpha reliability for prestige sensitivity was ranged from .78 to .98. The pilot test Cronbach's alpha was low .52 (Table 1). The price-based prestige sensitivity scales measures the degree to which people purchase higher price brands and product as an outward sign of prestige (Netemeyer, et al., 1995). Scoring is conducted on a five-point Likert scale (1 = strongly agree to 5 = strongly agree).

Purchase Intention

Purchase intention surveys give good forecasts of products (Whitlar et al., 1993). The instrument for measuring purchase intention is developed based on past research. Purchase intention measured using a scale adopted from Whitlar et al.'s (1993) study, with five level of intention. Reliability of pilot test for purchase intention was $\alpha =$

.63 (Table 1). Respondent were asked a general question about how likely they will purchase Malaysian-made products, using a Likert scale of five-point (1 = strongly disagree to 5 = strongly agree).

With regard to the issues of low reliability of purchase intention scale in the current study, we became somewhat concerned with our typical choices of words or phrases to describe purchase intentions. Mosteller and Youtz (1990) point out that some probability phrases appear to have more precise meanings than others. In their work, the probability categories such as "certain," "high chance," "even chance," "low chance," and "never" are much better terms than "definitely," 'probably," and "might." In particular, the "might/might not buy" often used for purchase intention surveys needs to be replaced by phrase such as "equally likely to buy as not buy," since everyone can truthfully answer that they "might or might not buy" (Whitlar et al., 1993).

In the study of product and service bundling decisions and their effects on purchase intention, Herrman, Huber, and Coulter (1997), for example, used the Likert scale of seven point for purchase intention, in which "1=Not likely to purchase" and "7=Very likely to purchase". The previous study has shown that various statement have been adapted in measuring and developing the purchase intention scale. Thus the selections of appropriate words may improve the reliability of purchase intention scale.

Demographic

Respondents' demographic information was obtained through series of questions on gender, age, marital status, household size, income level, and education level. This is to provide an overall impression about the population of interest.

Non-response Bias

In analyzing the questionnaire data, it is important that appropriate statistical tools are used, but before the data are analyzed, a test is conducted to detect the possibility of a non-response bias. The mailed questionnaire survey could suffer from a low response rate, which would give rise to a problem of non-response bias. A non-response bias occurs when only a proportion of the sample responds to the questionnaires and the responses are not representative of the samples (Wass and Wells, 1994). To overcome the problem of low response rate, the following methods were taken; a simple but attractive questionnaire in a booklet form, with cover letters printed on letterhead papers, self-addressed stamped, return envelopes, cover letters stressing the importance of the responses and giving assurance of confidentiality, and follow up.

Hypotheses

Based on previous research, we are interested in examining the link between consumer ethnocentric, materialistic attitude, prestige sensitivity, and purchase intention of Malaysian made products versus imported products. Past research demonstrates that consumers' willingness to buy a product thus be influenced by several variables. Further, we derived insight from the Fishbein and Ajzen's (1975) theory, which constitutes the overall conceptual foundation for our hypotheses. Demonstration of hypotheses could provide an important basis for benefit-based retailing and marketing strategies to tap the target market.

Consumer Ethnocentrism And Purchase Intention

This hypothesis is related to the effect of consumer ethnocentrism on purchase intention of Malaysian made products. Durvasula et al., (1992) mention that by examining the consumers' ethnocentrism, we could determine the strength and direction of ethnocentric beliefs that affect their purchase decisions of local products.

A series of nomological validity tests conducted in the USA by Shimp and Sharma (1987) indicated that consumer ethnocentrism is the moderate predictive of consumers purchase intentions on domestic products. They found that ethnocentric tendencies have significantly negative correlation with purchase intentions and attitudes towards foreign products. Netemeyer et al. (1991) reported that ethnocentric consumers have high tendency to reject imported products because they regard that nationalistic emotions affect their attitudes to purchase more of local products. In the current study we relies on the resumption that consumers' patriotic emotions significantly have positive effects on attitudes and purchase intentions of Malaysian-made products.

In mid 1997, Malaysia was severely affected by the outbreak of economic crisis. In response to the crisis, the government intensively encouraged consumers to purchase more of domestic product to stabilize the economy. Although this crisis had downturn the Malaysian economic performance, it has raised Malaysian consumers' patriotism to purchase more of local-made products in conserving the nation's wealth. It is conceivable that at least some Malaysian consumers will not purchase imports because of the moral implications on economic performance, no matter how attractive are the products. Devotion for one own country, fear of losing control of economic interests due to the harmful effects of purchasing imports and foreign competition make consumer to overestimate the quality and value of domestic products (Klein and Ettenson, 1999 Watson and Wright, 2000; Kaynak and Kara, 2002). As a matter of fact, this have encourage consumer to purchase more of domestic product versus imported (Han, 1988; Herche, 1994; Kucukemiroglu, 1999).

As one of the developing country, Malaysian should be continually progressed and cannot be daunted by economic deterioration due to heavy purchase of imported products by Malaysian consumers. Thus, ethnocentrism consumer implies that purchasing imports is wrong, unpatriotic, and results in loss of jobs in industries threatened by imports. Drawing from the above information, we suggest that consumer will respond positively to "buy the Malaysian-made products" as a moral obligation to purchase, and intense preference for domestic products. Since consumer ethnocentrism has been known as one of the antecedents that influencing consumers purchase intention on imported products, its is predict that:

> H1: Ethnocentric consumers are positively related to purchase intentions of Malaysian-made products.

Materialistic Attitude And Purchase Intention

Relying on concepts from the materialism literatures, we forward hypotheses that relate component of materialism with purchase intention. By linking the development of materialism concept to aspects of purchase intention, we hope to uncover a general mechanism capable of explaining why certain consumers are particularly dispassionate in purchasing Malaysian-made products. Dittmar (1992) views material possessions as material symbols and reflections of identity in terms of social-material status. This view of possessions and self-identity connects to positional goods, as both are quoted to explain a move away from buying domestic product to imported product (Dittmar, 1992).

Materialism associates with consequence of higher standard of living, where financial aspirations may push people to possess an important need for achievement in work, implying efficiency, diligence, and perseverance (Richins 1992). Materialism is considered a manifestation for life achievement given that it determines how people spend time and money and what they consider to be importance in their immediate surroundings. Taking into account that material possession is an involving activity, highly materialistic individuals are devoting more energy spends to purchase the products that they desire (Browne and Kaldenberg, 1997). These high involvement purchase process due to the extension of the information search in product attributes such as quality, design, and the best of workmanship in product and brands (Prendergast and Wong, 2003).

O'Shaughnessy and O'Shaughnessy (2002) claim that the orientation of modern capitalist societies is toward the marketing and consumption of goods with societal members extraordinarily concerned the accumulation of material possessions. For instance materialistic consumers in affluent capitalist societies would be content to spend more on luxury goods (Prendergast and Wong, 2003). Reasonably, people strive to own luxury products, by buying imported product to carve out some private dominions in which they can enjoy personal freedom. A case in point of Malaysian neighborhood, Singaporean, who are heavily influenced by western culture has shown a high materialistic orientation and look for the best of material comfort and money in their life (Kua, Kwon, Jiun, & Wirtz, 2000).

Indeed, this scenario had been occurred in Malaysia. When Malaysians' economic and social class varies widely and inevitable exist, people seek status and visibility in materials possessions that reflect their income level and life achievement. Undoubtedly today, materialism has increased dramatically among Malaysian society with sudden urbanization and commercialization, where drastic social changes have increased social mobility. This condition causes people to exposure more on foreign culture and their product usage, which increases the tendency of Malaysian to purchase imported products.

We anticipate that Malaysian consumer who are materialistic pursue their happiness through the acquisition of possessions that focus upon material achievement and connected with important others. Derived from the above explanation, we suggest that materialist attitude influence Malaysian consumers to consume more of imported product versus Malaysian-made products based on the perception that imported products express their

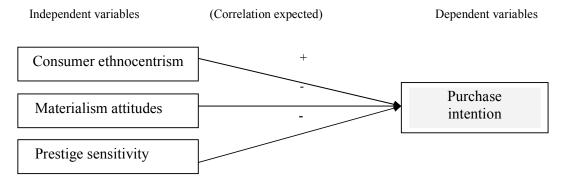
accumulation of material possession, which reflect their acquisitiveness identity, high purchasing power, and admirable life achievement. This conceptualization leads to the hypotheses examined:

> H2: Materialistic attitude consumers are negatively related to purchase intentions of Malaysian-made products.

Prestige Sensitivity And Purchase Intention

Our last hypothesis is on consumer prestige sensitivity that affects their purchase intentions of Malaysian-made products. Consumers with preferences for prestige favor products that reinforce their actual or desired for prestigious self-image and communicate this self-image to others. Prestige sensitivity is likely to be high among socially conscious group and affluent society who seek the symbols of status and power in their purchases. Consumers perceive a myriad of prestige cues, which include brand, quality, patron status, and store atmospherics (Deeter-Schmelz et al., 2000).

The assumption that the attributes of prestige products are infrequently purchased, require a higher level of interest and knowledge that are strongly relate to the person self-concept, and social identity. This assumption distinguishes themselves from others, and serves as a symbolic marker of group membership (Dawson, 1988). Prestige sensitivity consumers demand a high-involvement of purchasing process that necessitates the continual process of search, purchase, savoring, using and finally replacing goods (Vigneron and Johnson, 1999). This process is masking what is ultimately a search for social integration, which displays prestigious power and status. The reassurances consumers derive from prestige products actually enhance the value and pleasure of anticipation when they consume these types of products.

Buying imported products alleviate those consumers who are looking for prestigious products. Consumers prefer to purchase imported products because they are confident in the judgment of style, quality, design, exclusiveness, uniqueness, popular, expensiveness, precious, rare, limited, and scarcity of the kinds. The uniqueness and limited availability of imported products stimulates the pervasion of values by dramatizing the status satisfactions at the deepest levels through the products ownership. Social value of prestige products comes from the exclusiveness of limited product alternatives, and satisfaction arises in large part from a product's value.


The imported products could be inferred as the highest level of prestigious products encompassing several physical and psychological values such as perceived conspicuous, unique, social, hedonic, and quality. Consumers with preferences for high prestige may use relatively higher prices to infer prestige and quality (Lichtenstein et al., 1993; McGowan and Strenquist, 1998). Consumers are motivated by a desire to impress others with their ability to pay particularity high prices in exchange for superior quality of prestigious products (Braun and Wicklund, 1989). Prestige brand suggest superior product characteristics and quality performance whereby people relate the prestige product according to their personal values reassurance.

The increase in Malaysian consumers' disposable income inspires their purchasing power to buy imported products that represent prestigious symbols. To maintain their prestigious status, Malaysian consumers buy products with the advertising promise them the high value for social status from all over the world (Netemeyer, Burton, & Lichtenstein, 1995). As a matter of fact, consumers who learn about other cultures are likely to have the most profound effect on knowledge about other people lifestyles and increase receptivity towards foreign products. This receptivity creates positive attitudes on purchase intention of imported versus domestic products (Nijssen and Douglas, 1999).
The foregoing discussion leads to the following hypothesis:

> H3: Prestige sensitivity consumers are negatively related to purchase intentions of Malaysian-made products.

Figure 1: Correlation With Purchase Intention

Independent variables   (Correlation expected)   Dependent variables

The hypotheses were subjected to stepwise multiple regression analysis to find out the relationship of the predictor variables with the criterion variables. The consumers' purchase intention will be used as the ultimate dependent variable in this study.

The general structural equation that was employed to explain the relationship is:

Purchase intention $\quad\quad = \alpha + \beta^1$Consumer ethnocentrism $+ \beta^2$Material attitude $+ \beta^3$Prestige sensitivity $+ \varepsilon$

where:

Purchase intention $\quad\quad$ = purchase probability associated with an intention category at the percentage of individuals that will actually buy product

Consumer ethnocentrism = consumers' belief about the appropriateness and morality of purchasing foreign-made products

Material attitude $\quad\quad$ = value held by an individual, who embodies the importance one attaches to material possessions and their acquisition as a necessary or desirable form of conduct to reach desired end states including happiness

Prestige sensitivity $\quad\quad$ = favorable perceptions of the price cue based on feelings of prominence and status that higher prices signal to other people about the purchaser

α and βI $\quad\quad$ = constant/parameters to be estimated, i = 1 to 3, and

ε $\quad\quad$ = disturbance term

RESULTS

Instrument Characteristics

Before proceeding with the analysis, the items comprising the independent and dependent variables were examined for reliability. We used Cronbach's alpha to calculate the reliability for consumer ethnocentrism, prestige sensitivity, and materialism attitude on purchase intention (Table 2). Reliability coefficients ranged from .64 to .91 and were considered to be appropriate for further analysis. One may notice that the reliability for variables do achieve desired levels, with the exception of purchase intention.

The consistency of consumer ethnocentrism constructs ($\alpha = 0.91$) with previously reported research show high level of reliabilities alpha ranged from 0.91 to 0.96 (Shimp and Sharma, 1987; Netemeyer et al., 1991; Durvasula et al., 1992), thus giving evidence of internal consistency. Reported reliabilities for the materialism scale were $\alpha. = 84$ (Richins and Dawson, 1992) are consistent with the reliability reported in the current study (Table 2). The reliability for prestige sensitivity in the previous studies ($\alpha = .78$ to .90) lends support the use of this scale as measures in the current study with the $\alpha = .86$ (Table 2). We reverse code three items and deleted one item from purchase intention to improve reliability. Due to the low reliability of the prestige sensitivity items, the researchers reviewed each item critically, one at a time, to examine its theoretical appropriateness. Given that previous research does not provide clear direction on the purchase intention, the reliability analysis for the dependent variables, purchase intentions, was accepted at $\alpha = .64$.

Table 2: The Descriptive Statistics and the Reliability of the Independent and Dependent Variables

Variables	Mean	Standard Deviation	Alpha
Consumer ethnocentrism	3.19	.68	.91
Materialism attitude	2.88	.73	.84
Prestige sensitivity	2.90	.63	.86
Purchase intention	3.97	.68	.64

Sample Characteristics

A following step is taken by sending a reminding note through emailing address to respondents who are not filled and returned their questionnaires on 12 January 2004. Descriptive data statistics are relied upon to identify the respondents' characteristics. Of the 800 questionnaires distributed to the respondents, 274 (34.3 %) were returned. Of the entire returned questionnaire, 266 (33.3%) responses were usable for data analysis while 8 were discarded due to missing answers or apparent inappropriate response patterns. The percentage of respondents of the faculty staff of the overall population was identified through their position. Of the entire return questionnaire the percentage for professor/associate professor, lecturer, and instructor/tutor respective are; (33.0%, 33.3%, and 31.6%) (Table 3). The sample is assumed to be representative of the population. The detailed demographic information of the sample is presented in Table 4.

Table 3: Summaries the Data on the Questionnaires Distributed

Respondent position	Sent	Return
Professor/Associate professor	103	34(33.0%)
Lecturer	602	202(33.3%)
Instructor/tutor	95	30(31.6%)
NA (Discarded)		8(2.92%)
Total	800	274(34.3%)

Table 4: Profiles of Respondents

Variable	Percentage	Frequency
Gender		
Male	51.9	138
Female	48.1	128
Age		
20-40	72.9	194
41-60	23.3	62
Above 60	3.8	10
Marital status		
Single	26.4	70
Married	73.2	194
Single parents	0.4	1
Income		
RM1000-RM5000	84.5	224
RM5001-RM9000	13.6	36
Above RM9001	1.9	5
Position		
Professor	0.4	2
Professor with position held	0.4	1
Associate professor	8.7	23
Associate professor with position held	3.0	8
Lecturer	65.7	174
Lecturer with position held	10.6	28
Instructor/tutor	11.3	30

The gender of respondents was fairly evenly distributed with males (51.9%) and females (48.1%). The sample was composed of more age groups of 20-40 years old (72.9%). A greater percentage of the sample indicated that they are married (73.2%) versus single (26.4%). The majority of respondents (84.5%) had income between RM1000-RM5000. The largest group of respondent was lecturer (65.7%).

Non-Response Bias

As discussed earlier, a low response rate might give rise to a problem of non-response bias that might in turn cause the data to be unreliable or invalid. To establish the reliability and validity of the data, an effort was made to test the possible presence of non-response bias. Oppenheim (1992) suggested that one practical way to detect non-response bias is to compare the answers to the questionnaire given by early respondents with those of late respondents. In this study, the first 30 and the latest 30 questionnaires received from respondents respectively were categorized as earlier and late.

T-test was done to test the mean differences among the four variables (consumer ethnocentrism, materialism attitude, prestige sensitivity, and purchase intention). T-tests indicated no significant differences in the respondents' scores on variables from the two groups. The findings suggest that non-respondent would generally have the same opinion as those who responded. Thus, the data are considered representative of the population of both groups of respondents, and generalization may be made.

Hypothesis Testing

Bivariate analysis (Pearson correlation) was undertaken to examine the relationships in the research hypotheses. The result of the analysis is presented in Table 5.

Table 5: Summary of Hypothesis Test

Hypothesis	Hypothesized Direction	Result	Support
H1: Ethnocentric consumers are positively related to purchase intentions of Malaysian-made products.	+ve	+ve	Supported
H2: Materialistic attitude consumers are negatively related to purchase intentions of Malaysian-made products.	-ve	-ve	Supported
H3: Prestige sensitivity consumers are negatively related to purchase intentions of Malaysian-made products.	-ve	-ve	Supported

Relationship Between Consumer Ethnocentrism And Purchase Intention

Hypothesis 1 predicted a positive relationship between consumer ethnocentrism and purchase intention of Malaysian made products. The results of this analysis yield support with a correlation of $r = .000$ (Table 5). The extant literature indicates largely that ethnocentrism was found to be positively related to preference of domestic products over imported products (Sharma and Shimp, 1987). Yet, lack of statistically significant findings in the current study may be due to low interest in patriotic consumption (Kim and Psyarchik, 2000). Interestingly, the relationship is not significant although support detected that consumers show a high score in CETSCALE. This finding did not consistent with most of the relevant studies that show higher tendency for consumers to purchase domestic products. This give the evidence that even if Malaysian consumers are ethnocentric, yet they perceived that it is not wrong to purchase imported products. Our finding is consistent with Marcoux et al., (1997) who found that the effect of younger women having a low interest in patriotic consumption, inclined to use goods to aspire to a social status show a preference for clothing made in Western countries rather than local one. O'Cass and Lim's (2002) study found that young Singaporean consumers are more favorable on Western products (imported) than Eastern products (includes those Made in Singapore).

Relationship Between Materialism Attitude And Purchase Intention

Hypothesis 2 proposed a negative relationship between materialism attitude and purchase intentions of Malaysian-made products. Our results revealed support (r = -.136) at p = 0.05 level (Table 5). The relationship showed a negative correlation. This significant correlation may be possibly because they are favorably evaluate imported products with the assumption that imported products offer them the first-rate items, which associated with image status, wealth and personal achievement. The result support the idea that purchased imported

product would represent their attitude toward materialism and believe that possessions are an essential element of success to a person's existence, and an important role in achieving happiness in their lifetime.

Relationship Between Prestige Sensitivity And Purchase Intention

Hypothesis 3 predicted that prestige sensitivity would be negatively related to purchase intentions of Malaysian-made product. As the result shown in Table 5 this hypothesis is supported ($r = -.145$) at $p = 0.05$ level. As expected, the impact of prestige sensitivity on reluctance to purchase Malaysian-made products was due to believe that imported product make them feel classy and good about themselves. As people rate other people by the value of their prestige of products usage, buying imported product help to express their prestige status. The results indicate that Malaysian consumers prefer to purchase imported products in enhancing and aspiring their social status and prestigious lifestyles.

Table 6: Pearson Correlation Coefficients

Variables	Purchase intentions	Consumer ethnocentrism	Materialistic attitude	Prestige sensitivity
Purchase intention	1.000			
Consumer ethnocentrism	.000	1.000		
Material attitude	-.136*	.264**	1.000	
Prestige sensitivity	- .145*	.445**	.801**	1.000

Note:
**. Correlation is significant at the 0.01 level (2-tailed).
 *. Correlation is significant at the 0.05 level (2-tailed).

In order to determine the effect of consumer ethnocentrism, materialism attitude and prestige sensitivity on purchase intention, correlation and stepwise regression analyses were used to analyze the data. In the regression model, purchase intention was the dependent variable. However, in applying the regression model, a problem of multicollinearity may present among the variables. To determine the presence of any severe multicollinearity problems, each of the variables was alternately regressed on all other variables.

According to Kleinbaum, Kupper and Muller (1988), a model is said to suffer a severe problem of multicollinearity if the correlation is high or above $r = .9$. The possibility of the presence of this problem was initially determined in Table 6, which shows the correlation matrix of variables using Pearson correlation coefficients. As noted in Table 6, there was a high correlation between the two sizes variables (prestige sensitivity and material attitude). This high correlation signaled multicollinearity that might be a problem if both variables were included simultaneously in a regression model. However, the result of Deeter-Schmelz et al.'s (2000) study support our research's contention that material success, while distinct from prestige shopping, is a construct that expect to correlate positively and significantly with components of the prestige-shopping profile.

The data were subjected to stepwise multiple regression analysis to find out the relationship of the predictor variables with the criterion variables. The results found and apply for general structural equation that was employed to explain the association is:

Purchase intention $= \alpha + \beta^1$Consumer ethnocentrism $+ \beta^2$Material attitude $+ \beta^3$Prestige sensitivity $+ \varepsilon$

As previously mentioned, given the poor fit of the model, the researchers reviewed each item critically, one at a time, to examine its theoretical appropriateness.

Table 7: Summary of Stepwise Regression Result

Model	Variable entered	R2	Adjusted R Square	F-ratio
1	Consumer ethnocentrism	.053	.049	14.13
2	Material attitude	.068	.061	9.29

DISCUSSION AND CONCLUSION

The current study provides some implications for future research. The dimensions used in the current study involve consumer ethnocentrism, materialism attitudes, prestige sensitivity, and purchase intention. Ethnocentrism based on nationalism does not necessarily affect consumer perceptions of product quality and purchase intention. Also of importance is social status demonstration and interpersonal mediation of two variables; materialism attitudes and prestige sensitivity. Both of these two variables derive from the meanings of the conspicuous consumption scale. This finding provides some lesson and other immediate implications for marketing and retail management. A buyer, merchandiser, category and store manager, and salespeople make decisions regarding the mix of product categories are required a complete information and a thoroughly understanding of how consumer ethnocentrism, materialism attitude, prestige sensitivity, and purchase intention are likely to be perceived by a targeted market.

Consumer Ethnocentrism

The concept of consumer ethnocentrism may improve our understanding of consumer behavior, and why certain segments of consumer prefer domestic products, whereas others do not discriminate between domestic and imported products (Piron, 2002). Along with increased patriotism and heavy emphasis on cultural and ethnic identity, consumers' ethnocentrism will be a potent force in the global business environment in the years to come (Kucukemiroglu, 1999).

Deciding on the degree of ethnocentrism with which the companies wish to be associated and the geographical limits of its impact may be a factor in retail management achievement. These reasons support the interest in advancing as regards measurement instruments and, in addition, in the geographical delimitation of the effect of consumer ethnocentrism, which varies depending on product types and categories. For instance, ethnocentrism based on nationalism does not necessarily affect perceptions of product quality and purchase intention on domestic product (Watson and Wright, 2000). For some product, consumers certainly might rate home country product lower than outsider would rate them (Speece and Pinkaeo, 2002).

Understanding whether the level of ethnocentrism differentiate customer attitude towards Malaysian made and imported products is useful for the development of marketing strategies. Although Malaysian consumers are ethnocentric does not mean that they would only buy local made products. The implication is that knowledge of consumer ethnocentric tendencies could be used to position Malaysian-made products by customizing the marketing mix and product categories. This may force marketers and retailers to intensively promote more campaign for buying Malaysian product. These practices should help alleviate ethnocentric consumer to aware about the Malaysian-made product.

Fast changed in globalization lead consumer to demand a rapid product invention of imported product to satisfy their consumption needs (Kim and Psyarchik, 2000; Suh and Kwon, 2002). Thus, the result presented here provide a picture of those consumers who are likely to eschew and denigrate all foreign goods, versus those consumers who may view is not wrong to buy imported (Klein and Ettenson, 1999). Understanding this behavior require managers to build intensive marketing planning and consider how their marketing communications influence the consumers. This would help them to strategically identify and target those consumers who are most likely to respond favorably to marketing communications, which focus on domestic production or domestic imported themes (Klein and Ettenson, 1999).

Materialism Attitude

Materialism is associated with a greater drive to acquire the products that marketers provide for consumers. The ability of material possessions to serve different symbolic roles could be a basis for the success of some products and promotional campaigns tactics. It appears that a low interest in purchasing local product is the determining factor of the preference towards imported products. This is because materialism affect consumer attitude to focus on selection of products that truly related to acquisition and place high priority on their ownership and value indicators (Ryan and Dziurawiec, 2000).

The improvement of Malaysian standard of living and increase in income level has facilitated higher levels of consumption. These forces may therefore increase the general standard of living where materialism prevails to purchase imported products versus Malaysian-made products. Purchasing limited choice of imported products, make it becomes uniqueness, rare and precious in comparing to domestic products. This uniqueness of imported products helps them to distinguish themselves from others to show their best interest in materialism accumulation.

The relationship is likely to hold in countries like Malaysia with relatively open markets, where consumers have choice and information for making selection of imported product. Another possibility is that recently Malaysia has been an international center for trade and commerce with the establishment of international events, and increases in duty free outlets make people take for granted to purchase imported products. This situation may be tied to the fact that consumers will be more accepting of imported products as globalization is accelerated. Further, this information will enable international marketers to better understand how their offerings will be perceived in different segments of the global market, and to strategically target and position their products accordingly.

Prestige sensitivity

Shopping behavior based on the symbolic prestige qualities of products has long been accepted as ubiquitous in nature. The success of prestige strategy depends on the ability of marketers to identify and target consumers who purchase products. Targeting consumers who value prestige requires an understanding of the factors that underlie the acquisition of prestigious symbols. As the utility of prestige products may be to display wealth and power, one could consider that highly visible prestige-brands would dominate the conscious segment of the consumer (Vigneron and Johnson, 1999). Given the efforts of some retailers to position their products based on some notion of prestige, a reliable and valid measure of the set of factors that underlie prestige purchasing would be useful for them to identify prestige market segments and understanding what prestige means to consumers (Deeter-Schmelz et al., 2000).

We must understand the nature of prestige-shopping behavior before we can effectively quantify various prestige levels segments for any product category; more precisely in targeting niche market of prestigious consumer, and design appropriate prestige positioning strategies. As such, the prestige sensitivity profile resulting from our study should have several benefits to retail practitioners. The prestige sensitivity profile also could be used as a market segmentation tool and could help to facilitate more accurate estimates of the size of various prestige segments within a given area. Various prestige level gaps exist within a geographic require managers to justify a location for prestigious retail outlet. The estimates are critical with regards to store location, product mix, and positioning decisions (Dawson, 1988).

Prestige sensitivity also highlights the strategic importance of integrated marketing communications to ensure that the company sends out a consistent, clear message about the product's price, as its one of the indicator for product prestige sensitivity. Consumers who value prestige are more likely to pay higher for merchandise perceived as highly prestigious and pay higher margins demanded by retail outlets perceived as selective or exclusive distributors of that merchandise (Dawson, 1988). Exclusiveness and luxury brands are among the factors that influence prestige sensitivity consumer to purchase more of imported products over Malaysian-made products. This is because symbolic consumption is particularly relevant to stores using prestige brand. Brands and stores are sometimes repositioned to a higher prestige niche as a means to attract new markets and improve profitability (Deeter-Schmelz et al., 2000; Daneshvary and Schew, 2000).

In particular, more consumers are moving away from traditional low-cost local products to up market of luxury brands. This desire to impress others via the appearance of their prestigious status suggests an opportunity for imported products marketers to develop their product lines. The relative symbolic impact of friends, admired others, and wealthy people on prestige shopping might vary substantially among trade areas and segments defined by other demographic variables. Such knowledge would be very useful in helping retailers to improve profitability through their promotional planning, store location, number of outlet, and merchandising decisions.

Research Recommendation

For the research finding, it seems clear that ethnocentrism, materialistic attitude, and prestige sensitivity are part of consumers' emotional factors that played an important role in determining the consumers' purchase intention on Malaysian made and imported products. Trends towards the globalization of markets are fueled by changes in consumer knowledge, attitudes, behavior, and preferences (Suh and Kwon, 2002). Among other things, the findings provide evidence that there are differences in the attitudes and intention of respondents towards Malaysian-made-products. This finding also provides useful information for marketers of local goods as well as foreign marketers exporting to Malaysia in selecting their target markets and formulating appropriate marketing strategies.

The availability of numerous imported products categories in developing countries like Malaysia is tremendous, hence making the competition in the domestic markets becoming more rigorous and giving more choices to consumers (Abdul Razak et al., 2002). Thus Malaysian-made products begin to face stiffer competition with those imported items in capturing the spending budget of Malaysian consumers (Abdul Razak et al., 2002). Today's, we could observe that a number of Malaysian consumers are become familiar and more willing to consider imported products as an alternative to Malaysian-made goods.

Coupled with what marketers and manufacturers already know about the profiles of their target customers, understanding the antecedent of ethnocentric emotion, materialism attitude, and prestige sensitivity will enable them to segment and control their domestic markets more effectively. Marketers will be able to strategically identify and target those consumers who are most likely to respond favorably to marketing communications, which portray Malaysian-made products and local themes. Comparative advertising campaigns targeted at Malaysian consumers, with particular emphasis on products that reflect the local cultural values might enhance the consumers' perceptions of domestic products quality. For international marketers, this information will enable them to better understand how their offerings will be perceived by different segments of Malaysian market.

From a managerial perspective, the results are instructive for local and international marketers and manufacturers focus on educated consumers in Malaysia. Marketers of Malaysian-made products who compete with those international marketers may use the theme of patriotism in advertising and promotion. For international marketers, they should avoid sensitive aspect of patriotism and focus on social status demonstration.

In general, our findings suggest that, retailers of Malaysian-made products should adopt different strategies in different product categories to be successful in inducing the reluctant consumers to purchase local products. If consumers are reluctant to buy Malaysian-made product solely due to the perception of poor product quality, less prestigious, not represent achievement in material possession, and become globalize through their own initiatives and purchase more of imported products, the market penetration for Malaysian-made products may become relatively hard vis-a-vis easier for imported products.

Limitation and future research

Several limitations are, however, inherent in this study and these can limit the generalizability of the findings. A first limitation concerns external validity. A sample of faculty staff is not representative of the whole population. Since all respondents are white collars group of workers who having high level of education, thus the results cannot generalize to other groups of Malaysian consumers. Highly educated and cultural openness of the sample affects their ethnocentric, which make them tend to purchase more on imported product. Additionally, respondents who are faculty staff members are more urbanized, have a higher income, and they are experienced in study and travel abroad, which expose them more to foreign products, openness to cosmopolitan views and receptive to purchase imported products.

The second limitation is that in the future it might be interesting to observe if any of the demographic variables of the respondents might influence the purchase intention. Future research should be conducted using demographic variables as one of the independent variables. It might be interesting to observe if respondents and any of the demographic variables of the respondents might influence their purchase intention of Malaysian-made products.

The third limitation is that the current study examined a single product category and subjects were not provided with a context in which to frame their decisions about the importance of the products. Although furniture was chosen because other research has shown it to be useful for manipulating self-presentation, some of the results may be due to product choice and may not be generalizable to other product categories. Is it distinguishable with purchase intention to buy Malaysian-made products when they are assesses with many product categories? However, many other studies have used single products, and particularly fashion clothing (Browne and Kaldenberg, 1997; Flynn & Goldsmith, 1993; O'Cass, 2002).

ABSTRACT

Nutrition labels on food packages are designed to promote and protect public health by providing nutrition information so that consumers can be informed regarding the nutrient content and ingredients content on the food products. Therefore, an understanding of consumers' perception and attitudes towards nutrition information on food packages has important implications for public health and nutrition education. This study explores the association between reading nutrition labels and demographic factors on manufactured food packages. Health behaviour's literatures suggest that perceived benefits and costs of using nutrition labels and perceived capability of using labels are associated with consumers' profile. The relationship between reading nutrition information and consumers behaviour was estimated by logistic regressions. Survey was undertaken, 1200 respondents were interviewed vie questionnaires to gather information regarding their perception towards nutrition labelling. The results show that there is strong relationship between consumers' socio-economic profile and reading nutrition labels.

INTRODUCTION

Iran has invested about USD500 million in establishing more than 300 food-processing plants. Food processing in its modern sense is relatively new to Iran and the government is taking steps to promote this aspect of agro-industrial growth including the granting of low interest loans for investors. With population of near 61 million and per capita GDP of US$1800.974, the potential of food processed and food production is tremendous. New investment in food processing industry has been on the rise and one of the main concerns of Iranian government is to insure food safety, quality and the introductions of assurance system in order to meet consumers' demand for health and wholesome food product. Due to the recent development in food industries in Iran and the increased dependency on packaged foods, there is rising need for providing nutrition information on food labels to enable Iranians consumers and others to make informed food purchasing decisions for healthy living. Nutrition labelling is to be considered as the regulatory status of foods that can be made regarding to health promoting properties, with emphasis on the situation of the manufactured products. According to Berner (1998) nutrition label can approve the health claim, which made by producers in terms of healthy products. The nutrition labels provide important information to help people make food-purchasing decision in an informed manner. Increasing interests in the relationship between diet and health has led to an ever-sharper focus on nutritional aspects of the food supply. Today people are becoming increasingly health conscious and are making demands for more nutritionally well balanced diets than any time in history (Levy et. al, 1998). The growth in consumer demand for high-quality products is causing changes in the functioning of the food processing and marketing sector. Like the other countries, there is need to established regulatory bodies in Iran, to monitor nutrition labelling in food manufacturing to ensure that whatever being claimed is accurate and true. At the same time designing nutrition labelling is a policy to achieve a social objective like a healthier population (Golan, 2001).

HISTORICAL DEVELOPMENT OF NUTRITION LABELLING

The US was one the first country that introduced nutrition labelling. In the US there are three main groups of legislators that cover food labelling and nutrition fact labelling for the purpose of protecting consumer's interests: United State Department of Agriculture (USDA), Food & Drug Administration (FDA) and Nutrition Labelling and Education Act (NLEA). Under the provision of the new Act, by May 1994 all of the food manufacturing companies were required to use the new food and nutrition label as a mandatory program. A key element of the new nutrition label was the "Nutrition Facts" panel that gives consumers significant information about the nutritional content of foods. For example, the Percent Daily Value column tells consumers in bold print whether the food is low or high in the key nutrients, fat, saturated fat, cholesterol, sodium and

carbohydrates. In addition to "Nutrition Fact" panel, label claims like "lite" or "reduced fat" must meet standard definitions and must have reconfirmed in nutrition labels (Neuhouser *et. al.,* 1999).

After the US many countries have pursued programmes in nutrition information. In Canada, first, nutrition labelling was introduced to the food producers as a voluntary programme. However under the new published regulation in January 2003, for the most processed food, nutrition labelling accommodating is mandatory. In 1996 the Food Advisory Committee (FAC), United Kingdom completed its review of the British market for functional foods and the control of health claims. The scope of this was that they applied to all food and drinks, including food supplements. A food claim is defined in the draft as any statement, suggestions or implications in food labelling or advertising that food is beneficial to health. Because of the integral relation between food, health and the capacity of food labelling to convey information to consumers, Food Standards Australia New Zealand (FSANZ) has reviewed its food regulatory. FSANZ's primary objectives in developing food regulation are: the protection of public health and safety; the provision of adequate information relating to food to enable consumers to make informed choices; and the prevention of misleading or deceptive conduct (Lewis & Jefferson*, 2000). Asian countries are likely to embrace higher labelling standards. For example additional labelling laws may require open dating (to describe product freshness), unit pricing (to state the product cost in standard measurement unit), and percentage labelling (to show the percentage of each important ingredient) (Kotler, 1999). It is possible to consider the last point as nutrition facts. But still this programme is voluntary in the most countries in the world. Hong Kong specifics that manufactured food "shall be marked or labelled with a list of nutrient and listed in descending of weight and volume. It requires these labels only on manufactured food (Yeon, 2003). Malaysia in September 2003 developed the nutrition labelling issues, which required a wide range of manufactured product should accompany by nutrition label (WHO 2004).

NUTRITION LABELLING IN IRAN

In 2000, Iran Health Ministry and Iran Institute of Standard and Industrial Research of Iran (ISIRI) have made considerable progress, with regard to nutrition labelling. The authorities recognized that a comprehensive education initiative is necessary to support the appropriate use of this nutrition labels and maximize its potential to assist Iranians in making informed food choices. According to the nutrition labelling Act 2000, the nutrition labelling is voluntary for manufactured food products but if the health claim is made or the additives are used nutrition labels accommodation is mandatory on the food-manufactured package. With a good knowledge of the quality of the food people take, they will able to choose the best items. The nutrition labelling has become the most widely available source of nutrition and food content information used in Iran today. However, there is real potential for information on the food label to be confusing or even false or misleading. The problems like misbranding, illegal adulteration and false claims in food products have become important challenges to Iranian consumers. Previous research conducted, some of the barriers on reading the nutrition label by consumers were the difficulty of including reliable, representative data; inadequate information technology infrastructure among users; lack of user knowledge about nutrients and foods and weak literacy and mathematical skills among some users Cunningham *et. al.,* 2004). Health and diet related attitudes, special diet status, perceived importance of product attributes like nutrition and ease of preparation, race, gender, income, and body mass index are important factors affecting consumer's perception and beliefs about label used (Rodolfo 1999). Wailes (1996) found that women were more interested in reading label than men, checking the label for level of sugar, salt, cholesterol, fat, additives and nutrients. However nearly 50% of people said they did not believe the nutritional claims on the package, and 82% of buyers found it difficult to understand.

The main objective of the study is to find the relationship between the socio-economic of responders' profile and their acceptance of nutrition labels in manufactured food products. The problem here is people can understand and read nutrition labels; either can they influence by the source of nutrition information during purchasing food products or they find it as a way for the producers to promote the healthy food products. This study explores the impact of consumer's profile towards reading nutrition labels.

DATA AND METHODOLOGY

This study used data from a national survey of public attitudes towards various issues pertaining to the use of nutrition labels on manufactured food products. The questionnaire included subjects such attitudes toward nutrition labelling, perception toward nutrition labelling, awareness toward nutrition labelling and reason for using nutrition labelling. Information was also collected on consumers' socio-economic and value characteristics. These included data on age, education, income, gender, employment status and family size. The survey was conducted during April-May 2004, in Tehran province (Iran). One thousand and two hundred respondents were interviewed in order to obtain their attitudes and perceptions toward nutrition labelling. A

random sampling method was used in this research because it is necessary to obtain information from random groups of people who can provide the desired information.

A list of 30 questions relating to consumers perceptions and attitudes of nutrition labelling on the manufactured food were selected for this analysis. These questions explored how people valued the potential benefits that nutrition labels could bring to society, their perception of risks associated with the use of nutrition information labels, as well as their views about government associated with nutrition labelling development. Respondents were presented with various issues relating to the use of nutrition labels during food purchasing, and were asked to rate their agreement or disagreement on a scale of 1 to 5 (1 representing strong disagreement and 5 representing strong agreement).

Logistic model was used to predict the relationship between a binary response (yes/no) and socio-economic factors. Logistic regression analysis examines the influence of various factors on a dichotomous outcome by estimating the probability of the event's occurrence. The general form of regression model is as follows:

$$Z = \beta_0 + \beta_1 x_1 + \beta_2 x_2 \ldots\ldots + \beta_p x_p$$

Where

Z = the linear combination
B_0 = Constant
$\beta_1, \beta_2, \ldots\ldots \beta_p$ are partial regression coefficients.
$x_1, x_2 \ldots\ldots x_p$ are the independent variables.

In this research there are two dependent variables:

Z_1 = Influenced by source of nutrition information during buying food product

Coded as follows:
0 = non- influenced
1= influenced

Z_2 = Reading nutrition labelling during purchasing manufactured food

Coded as follows:
0 = not reading
1 = reading

The independents variables are as follows:

x_1 : Area
x_2 : Gender
x_3 : Age
x_4 : Marital Status
x_5 : Education Levels
x_6: Income Status

RESULTS AND DISCUSSION

The empirical results and discussions are presented in the following two subsections. First, demographic analysis to find the background of the respondents, second, The next subsection predicts the relationship between a binary response (yes/no) and socio-economic factors by logistic regression.

Descriptive Analysis

Respondents were selected from all major parts of Tehran, Karaj, Lavasan, Damavand. Mostly they were selected in the super markets, universities, clinics, and companies and even randomly in the public locations. The respondents were asked about their residential area, which was urban (Tehran) and suburb (other areas). As shown in Table 1, the numbers of respondents from urban and suburb were 808 (67.3 percent) and 392 (32.7 percent) respectively. Most of the respondents were females 621(51.8percent) as compared to male 579 (48.3 percent). Majority (67.4) of respondents interviewed was under 40 of age and most of them (86.3) were

educated more than secondary school. From 1200 of the respondents, 500 (41.7 percent) were single and 700(58.3 percent) were married. Occupation is of the important point in decision-making and marketing study. The occupation in this study divided into seven levels. Most of respondents had working experiences in a various positions such as working for government sector 227 (18.9 percent), private sector 271 (22.6 percent), self-employed 216 (18 percent), retired 77 (6.4 percent) and the others were students 162(13.5 percent), house wives 168 (14 percent) and unemployed 79 (6.6 percent) as a group of people are not financially independent.

In this study 763 (63.6 percent) respondents' income was between Rls2000 to Rls6000 (per month). This is the average range of income among Iranian family. On the other hand there were some families' income more than the average range Rls6001- Rls8000 179 (14.9 percent), Rls8001- Rls10000, 89(7.4 percent) and Rls10000 above, 88 (7.3 percent) and some less than 2000,81 (6.8 percent) of respondents. The number of household was between forty-on to fifty-six years old, 659 (54.8 percent) was the highest populations of respondents followed by twenty-one to thirty years old group, and 657 (43.8 percent). According to Statistical Centre of Iran the large group of population among Iranians is between twenty to thirty years old and also the average salary is between RLs2500 to Rls 3500.

Logistic Regression Analysis

In order to determine the relationship between demographic factors with reading nutrition labelling and purchasing food product influenced by sources of information, logic model was used. Thus, the analysis investigated two aspects such as analysis the significant demographic factors in determining the reading nutrition labelling and whether the consumers influence by the sources of information during purchasing food product.

The Relationship between Demographic Factors and Reading Nutrition Labels

According to the estimated model for the first dependent variable (reading nutrition labelling or not), there were four variables found significantly and positively related to the dependents variable to determine the choice between reading nutrition labelling or otherwise. Those were area, gender, and income and education level. The impact of residential area is significant which means the people who live in urban read more nutrition labelling than suburb areas. There is significant relationship appears between gender and reading nutrition labelling, which shows that female read more compared to men. The positive coefficient of indicated that education level (bachelor above) gives higher possibility to read nutrition labelling. The income coefficient was found positive and significant, it implies that an increase in income gives the higher prospect to read nutrition label. The results show that the estimated coefficient for above variables was positively significant at the 5 percent level. However the age of household (above ten) in the family were effecting the reading of nutrition label, but there was negative coefficient which, indicated an increase in the age and the members of family gives a lower probability to read the nutrition label according to study.

Other demographic variables, "age" and "marital status" were also included in logic model but the coefficients of these two were found insignificant. The results of the logic model analysis are shown in Table 2, Based on regression diagnostics, it seems the model is quit fit the data well. The percentage of right prediction was estimated to be 0.7025, which means the ratio of the probability that consumers will read nutrition labels, is 70.2%.

Table 2: Relationship between demographic factors and reading Nutrition label

Variables	Estimated coefficient	T-Ratio
Constant	-1.197	-3.55519 **
Area	0.446822	2.88238**
Gender	0.621754	4.536**
Age	0.00803527	1.23204
Income	0.000083	3.05243**
Education Level:		
Bachelor	1.45119	8.91331**
Master	1.47189	7.59513**
PhD	1.87671	6.10899**

Adult	-0.248201	-4.51521**
Macffaden R^2	0.16042	
Log likelihood function	-687.9592	
% of right prediction	0.7025	

Note: ** indicates significant at 5 percent level

Relationship between demographic factors and influenced by source of information

Second dependent variables that was estimated by logic analysis, was whether consumers influence by information that they received from the sources of nutrition information during purchasing manufactured food. There were three variables found which had significant and positive relationship with dependence variable. They were gender, age and education level (only with bachelor and master degree). The positive coefficient of gender indicates that females are more influenced by what they found from sources of information during buying food products, either age which has positive impact on purchasing manufactured food based on gained nutrition information from resources. In the other world by increasing the age, people are more interested to buy their food product based on the nutrition information which gained from nutrition information sources. The level of education was another factor that related to peoples knowledge. According to survey only the educated groups who are holding bachelor and master was found significantly and positively related to the dependent variables. The results have not shown the significant relationship between very highly educated groups and dependent variable. This was happened because mostly highly educated groups (PhD and medical doctor) they have enough knowledge and information on the other hand it is very difficult for them to accept the things which are not approved academically or technically and they are also pre-occupied with work. How ever the member of household (in every age) in the family was found significant with variables, but there was negative coefficient which, indicated an increase in the members of family gives a lower probability to influenced by source of information. It could be related to the life cost. Normally by increase the member in the family the cost life is going high, so far for the average large families the chance to take healthy diet could not be very easy.

Other demographic variables, "income" and "marital status" were also included in logic model but the coefficients of these two were found insignificant. The results of the logic model analysis are shown in Table 3.

Table 3: Relationship between demographic factors and influenced by source of information

Variables	*Estimated coefficient*	*T-Ratio*

Note: ** indicates significant at 5 percent level

CONCLUSIONS

By referring to the results, majority of respondents were from urban area and married. Generally most of the respondents were females, under 40 years- old and educated more than diploma level. This is consistent by the study have been done by Neoushouser *et. al.* (1999), significantly higher users of nutrition label are almost women and the consumers under 35 years and those with higher than diploma. The finding of the study reveals that income, education levels, residential area and gender are the most vital and significant factors that influence the nutrition label reading behaviour, thus, should be able to assist the government and food producers in taking into consideration the products market potential in near future. Moreover, it can be concluded from results; demographic factors can affect the consumers' behaviour during purchasing food products. Whether they read the label or not, understanding nutrition label and purchasing food products based on nutrition information are affected by their socio-economics factors.

The result of the regression analysis show that most of the variables in the equation have the expected prior sign, indicating the relationship between these variables (residential area, gender, income, education levels, family household) and the dependent variable –(1) reading nutrition label (2) influenced by source of information. The result indicate that gender, income, area and education levels increase the reading of nutrition labelling and for second dependent variable the results show that gender ,age and education levels increase the influenced by source of information. Hence based on a consequence and compare with the results from other methods, it can be concluded that economically and statistically, the results are accepted to be a model of analysis and calculation of perception towards nutrition labels.

Although the awareness of health conscious is increasing, but still for a large group of consumers is not easy to understand the information which, are provided by nutrition labels. As the matter of fact, Iranian government, and related institutions should fulfil the needs of consumers especially in the aspect food health management and consumers' health requirements. Improving the public awareness and developing the standard control measures to ensure correct labelling, which is intend on the producers, will increase purchasing based on nutrition labels.

The Global Challenges of Management Influence Tactics Option for New Technology Adoption in Business Enterprises

Kuan Huai Ly, Noornina Dahlan, Mahfooz A. Ansari

ABSTRACT

The current waves of globalisation challenges force organisations to adapt to technological change in order to sustain competitive advantage. New technology change may include significant changes in the tools, procedures and attitudes of the present employees. The key to combat this problem is the Technological Change Agent, who initiates and implements new technology; thereby overcoming any resistance from potential users. Using power-influence leadership theory, this study investigates the relationship between resistance and change agent's influence tactic in implementing the new technology. In general, the study confirms that there is no single best influence tactic for all situations. The effectiveness of a single tactic (soft, rational, or hard) is differently related to the resistance level (high or low). Specifically, the study finds that the change agents need to identify user's resistance level and to select the best-fit tactic for that particular user in that given situation. Importantly, the study shows that gender plays a significant role in the effectiveness of influence tactics. Men and women change agents use different tactics, depending on the user's gender. The study concludes that the selection of the best-fit influence tactic option depends on the gender of both the user and change agent, and the user's resistance level.

INTRODUCTION

Globalisation is the phenomenon of the increasing interdependency between markets; opening themselves to other markets, the objects of trade being capital and goods, including culture. To sustain competitive advantage, organizations need to be creative, innovative and adaptive to change. Technology, on the other hand, creates the competitive advantages and vast global opportunities for organizations (Laudon & Laudon, 2002). Globalization has made these technological changes even more rapid and unpredictable (Eisenhardt, 2002). In doing so, new technology and information systems are being introduced and initiated within the organization. There are ample evidences to demonstrate that a user's perceptions of a new information technology can have critical impact on the degree whether an implementation effort succeeds or fails (Abdinnour-Helm, Lengnick-Hall, & Lengnick-Hall, 2003). Maurer (Maurer, 1996, as cited in Gray, 2002) asserted that only one-third of major technological changes in organizations are successful; new technology failures are mainly caused by those who resisted change. Change is a constant element in the successful organisations. The effects are not limited to the environment alone but more importantly the human lives. Resistances to changes are due to fear of losing – security, pride and satisfaction, freedom, responsibility, authority and status. Management cannot assume that users willingly adopt or use the new technology without any form of resistance (Burton, Leitch, & Tuttle, 2001) - an illegitimate behavior and an attack on the organizational interests (Boonstra & Gravenhorst, 1998).

NEW TECHNOLOGY ADOPTION AND USER RESISTANCE

Breham (1966) defined resistance as 'an aversive motivational state, initiated when one perceives that ones' freedom is threatened, and directing thought and action toward regaining the threatened freedom'. Similar to attitude, resistance include three components: an affective component ("I don't like it!), a cognitive component ("I don't believe it!"), and a behavioural component ("I won't do it!") (Knowles, Butler, & Linn, 2001). People resists major changes in organizations because of lack of trust; belief that change is unnecessary; belief that the change is not feasible; economic threats; relative high cost; fear of personal failure; loss of status and power; threat to values and ideals; and resentment of interference (Yukl, 1994). To explore resistance to new technology, it is necessary to understand the concept of technology acceptance. The technology acceptance model (TAM) (Davis, 1985) considered two antecedents—perceived usefulness and perceived ease of using information technology. There is significant evidence (Davis, 1989; Davis, Bagozzi, & Warshaw, 1989; Mathieson, 1991; Taylor & Todd, 1995; Benedetto, Calantone, & Chun Zhang, 2003; Liaw & Huang, 2003) to support the TAM; some in the Malaysian context (Dahlan, Ramayah, & Looi, 2003; Dahlan, Kalthum, Ellitan, & Dahlan, 2003; Ramayah, Dahlan, & Adni, 2003; Wong, 2003). Positive attitude to technology adoption led to increased technology use (Compeau and Higgins, 1991; Lucas, 1975; Robey, 1979; Liaw & Huang, 2003;

Ramayah, Noor, Nasurdin, & Lim, 2002; Ramayah & Jantan, 2003). Hence, it is crucial to shape the positive attitudes towards technology adoption in determining new technology information system implementation effectiveness. Herold, Farmer and Mobley (1995) suggested that pre-implementation attitude towards technology is the initial attitude that shapes future implementation phases. It is important to understand the nature and origins of such attitudes, and factors that affect them. Rather than mandating usage, management could implement more effective social influence strategies. Information system may produce desirable outcomes even when user attitudes are unfavourable; but, the system may produce even better outcomes when user attitudes are favourable (Abdinnour-Helm et al., 2003).

INFLUENCE TACTICS

To offset resistance, management should adopt influential power that focuses on the capacity of the 'agent' to influence the 'target' (Yukl, 1994). Kipnis, Schmidt, and Wilkinson (1980) described 'influence tactics' as behaviours of an agent to gain from the target, while Ansari (1990) suggested that behaviours based on available resources are important for successful influence tactics. It involves attempts by the agent to change the behaviour, attitudes, or beliefs of the target (Castro, Douglas, Hochwarter, Ferris, & Frink, 2003). Importantly, agents must be conscious of typical effects of the choice and understand the most logical and effective choice of tactics used (Anderson, 1998). Different uses of influence tactics are studied: effectiveness (Kipnis et al., 1980; Yukl, Guinan, & Sottolano, 1995); target's hierarchical position (Kipnis et al., 1980; Yukl & Tracey, 1992); direction of influence—upward, downward, or lateral (Yukl and Falbe, 1990); and the importance of individual and contextual determinants of tactics (Ansari & Kapoor, 1987; Yukl, Falbe, & Youn, 1993). Kipnis and Schmidt (1985) suggested that influence tactics are grouped into three types: hard, soft, and rational persuasion. Hard tactics demand authority and position power, and they tend to be impersonal and manipulative. Soft tactics include personal power and power sharing (Falbe & Yukl, 1992), while rational tactics entail reasoning and rational persuasion (Kipnis & Schmidt, 1985). Usage of rational and soft tactics is regarded as fair interpersonal treatment (Tepper, Eisenbach, Kirby, & Potter, 1998). In contrast, harder tactics are less friendly and less socially desirable than the softer varieties that allow some freedom for the target (Kippenberg & Steensma, 2003; Yukl & Tracey, 1992). For example, pressure is used mostly to change the behavior of a subordinate, and it is used to acquire personal benefit from a superior. Kipnis et al. (1980) found that pressure is used after encountering initial resistance; more administrative sanction and personal action are more likely to be used when there is non-compliance and resistance to requests. However, hard tactics such as demands, threats and control generally pursue poor performance (Gavix, Green, & Fairhurst, 1995) and are frequently used in change process, while rational persuasion and coalition tactics aim to attain support from peers and superiors for major policy change (Gravenhorst & Boonstra, 1998). Further, change agents are more likely to use demands and threats, but less likely to use reward when they are insulted by the targets (Carothers & Allen, 1999).

NEW TECHNOLOGY ADOPTION AND INFLUENCE TACTICS

Individuals often view organizational change as a threat, unless change agents are able to influence and change user's attitudes, roles and skills (Yukl, 1994). In the context of technology adoption, the 'technological change agent' (who initiates and implements the new technology) confronts varying level of resistance from potential users. There are very limited studies that demonstrate the relationship between influence tactics and user resistance to technology adoption. During the technological change process, change agents use different tactics in responding to resistance level and they need to enhance their abilities to 'read' or diagnose different situations and select suitable influence methods (Lee & Sweeney, 2001). It is therefore crucial for the change agent to understand the effectiveness of an influence tactic on the resistance level towards technology adoption. This is vital to the success, and even survival of the firm (Enns, Huff, & Golden, 2003). Change agents are frequently required to spend much of their time attempting to convince and influence others to commit to strategic technology projects (Lederer & Mendelow, 1988). During the influencing process, attention should not only be paid to 'how' the tactic is implemented but also to 'why' the tactic is used (Hughes, Ginnett, & Curphy, 2002). There could be several reasons for selecting one or more possible tactics that had led to successful outcome more frequently than others (Hughes et al., 2002). Yukl et al. (1995) suggested that managers vary their tactics depending on the goals of the influence attempt; to help the organizations instigate strategic technological change that is expected to provide significant organisational benefits.

GENDER AND INFLUENCE TACTICS

Research on target's gender and influence tactics seem inconclusive. Ansari (1989) found that ingratiation (soft tactic) is more likely to be used on male targets, who are more influenced by the agent's expertise (rational tactic) compared to female targets (Liew, 2003). Given the extensive role of technology in business and the

increasing presence of women in the professional domain, it is important to understand gender differences of change agents in effective use of influence tactics (Venkatesh, Morris, & Ackerman, 2000). Stahelski and Paynton (1995) and Kipnis et al. (1980) found no significant gender differences for any power base or influence tactic use in any condition. However, previous studies indicated that men and women use different influence tactics. Men tend to use masculine strategies (threats or rewards) to resolve conflicts (Dubrin, 1991), and masculine individuals are more willing to use threats to resolve conflicts (Carothers and Allen, 1999). Generally, men tend to react more strongly when insulted, and they switch from reward to coercion, while females continue to use request when insulted (Carothers & Allen, 1999). Further, male managers use more direct strategies (such as coercion) to influence subordinates (Hirokawa, Kodama, & Harper, 1990), and authoritarian men prefer to use assertiveness and bargaining (exchange) more frequently because they probably identify themselves with institutional authority (Rajan & Krishnan, 2002). In addition, Mai-Dalton and Sullivan (1981) suggested that leaders are more likely to use reward and exchange tactic for subordinates of their own sex rather than for the opposite sex. Interestingly, Liew (2003) found that if both the target and change agent are the same sex, there will be more instrumental dependency and personalized exchange tactics. In contrast, female change agents use rational reasoning and upward appeals more frequently than males (Lee & Sweeney, 2001) possibly because hard influence tactics (assertiveness and upward appeal) are less effective when employed by females (Castro et al., 2003) as they generally lack the expertise and legitimate power (Carli, 1999). Further, Falbo (1977) found that females are more likely to use emotional tactics (such as tears) to influence others.

RESULTS

So, do the change agents use the same particular influence tactics when dealing with different levels of user's resistance? Or, they vary the use of the influence tactics in different situations (high or low resistance)? What determines the final choice among various tactics? This paper presents an empirical study assessing six influence tactics in responding to various resistance levels, and examining the influential effectiveness on future technological implementations. Further, this paper highlights the impact of gender of the user, gender of the change agent, and the interaction among variables, on the use of influence tactics. A total of 800 questionnaires were distributed; of which, 283 sets were completed and usable.

We conducted 5-step hierarchical multiple regression for the data analysis. In step 1, tenure with the current change agent was entered and it acted as control variable as an individual's choice of influence tactics was dependent on the individual's relationship with the target (Falbo & Peplau, 1980). Secondly, the direct effect of resistance level was entered (step 2), and then followed by dummy variable for gender of user and change agent (step 3). Subsequently, a total of nine two-way interaction terms (interaction between resistance level and user's sex; interaction between resistance level and change agent's sex; and interaction between user's sex and change agent's sex) were entered. Lastly, four three-way interaction terms (interaction among resistance level, user's sex, and change agent's sex) were entered. The hierarchical multiple regression analysis was carried out for each dimension of influence tactics. Table 4 reports a summary of hierarchical regression analysis.

As shown in Table 1, the control variable of tenure with change agent did not significantly affect the use of influence tactics. The direct effect of predictor—user's level of resistance (step 2) accounted significantly for a total of 5%, 21%, 6%, 5%, 11%, and 9% the variance, respectively, in personalized exchange, expert help, rational persuasion, upward appeal, assertiveness, and reminding. The findings reveal that level of resistance regarding overall set up negatively related the use of personalized exchange, expert help, assertiveness, and reminding tactic. In addition, level of resistance regarding value negatively related the use of expert help, rational persuasion, upward appeal, assertiveness, and reminding tactic. But, level of resistance regarding timing positively related to the use of upward appeal, assertiveness, and reminding tactic.

For step 3, both direct effect of predictor—gender of the user and gender of the change agent were found to be insignificant in predicting the use of influence tactics. Of interest were significant 2-way interactions (step 4) between level of resistance and user's sex for personalized exchange tactic and expert help tactic. The first interaction [see Figure 1(a)] revealed that, at low level of resistance regarding value, female users would encourage their change agent to use more of personalized exchange tactic. However, when the level of resistance of the female users increased, the use of personalized exchange by their change agent decreased.

Table 1 : Summary of Hierarchical Regression Analysis

		Model

Note. * $p < .05$, ** $p < .01$; [R] Dummy Coded (0 = Female, 1 = Male); Model 1= Personalized Exchange; Model 2 = Expert Help; Model 3 = Rational Persuasion; Model 4 = Upward Appeal; Model 5 = Assertiveness; Model 6 = Reminding

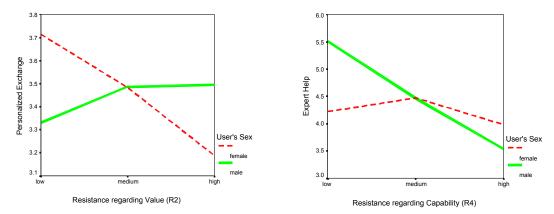
Besides, personalized exchange was more likely to be used to the male users in responding to their high level of resistance regarding value, as compared to female user. On the other hand, Figure 1(b) indicated that at low level of resistance regarding capability, male users were influenced more with expert help, as compared to female users. The higher their level of resistance, the lower would be the use of expert help by their change agent. Female users were influenced at the same extent of expert help tactics regardless their level of resistance regarding capability.


Figure 1: Interactions between level of resistance and user's sex on influence tactics.

In the case of interaction between level of resistance and change agent's sex, Figure 2(a) indicated that the tendency to use expert help tactics by both male and female change agent was decreased as the level of resistance increased. At high level of resistance regarding overall set up, female change agents displayed higher extent in using expert help tactic as compared to male change agents. On the other hand, for the high level of resistance regarding timing, male and female change agents did not differ significantly in terms of the use of expert help tactics. But male change agent reported significantly more frequent use of expert help tactics than male change agent when the resistance level is low [see Figure 2(b)]. In analysing the interaction between user's sex and change agent's sex, Figure 3 illustrated that if both user and change agent were of same sex, the higher the use of personalized exchange was observed.

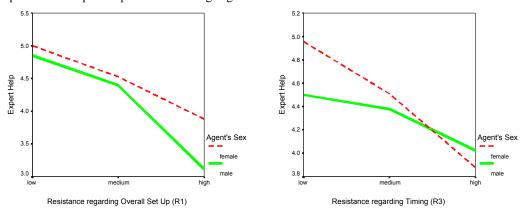
Besides that, three-way interactions among the predictors can be seen from the graphical presentation at different levels of resistance on expert help, rational persuasion, upward appeal, assertiveness, and reminding as shown in Figures 4 – 8. The first interaction [see Figure 4(a)] illustrated that, male change agents, as compared to female change agents, made more frequent use of expert help with female users at high level of resistance regarding value. To the contrary, female change agent reported significantly higher on expert help than the male change when responding to male users at high level of resistance. On the other hand, when dealing with both female and male users at low level of resistance regarding value [see Figure 4(b)], female change agents made more frequent use of expert help than male change agents.


Figure 2: Interactions between Level of Resistance and Change Agent's Sex on Influence Tactics.
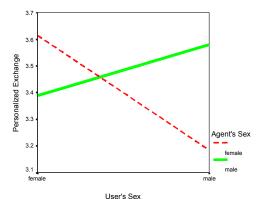

Figure 3: Interactions between User's Sex and Change Agent's Sex on Influence Tactics.
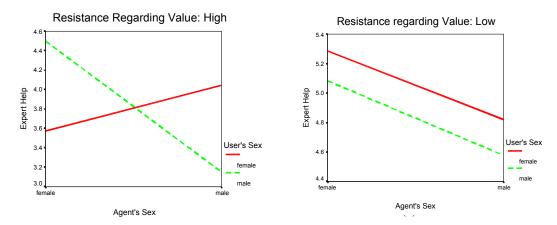

Figure 4: Interaction among Resistance regarding Value, User's sex, and Change Agent's Sex on Expert Help.

The second interaction [see Figure 5(a)] revealed that, when resistance regarding value is high, male and female change agents did not differ significantly in terms of their use of rational persuasion tactic with their male users. However, when confronted with female users at high resistance, male change agents become distinctly higher in using rational persuasion tactic as compared to female change agents. On the other hand, at low level of resistance regarding value [see Figure 5(b)], male change agents, as compared to female change agents, showed greater tendency in using rational persuasion tactic with their male users; to the contrary, they showed lesser tendency with their female users as compared to female change agents. At high level of resistance regarding value [see Figure 6(a)], both male and female change agents reported same extent in term of their use of upward appeal with male users. However, male change agents, as compared to female change agents, made significantly higher use of upward appeal tactic with their female users. At low level of resistance regarding value [see Figure 6(b)], male (female) change agents, as compared to female (male) change agents, showed greater tendency in using upward appeal tactic with their male (female) users.

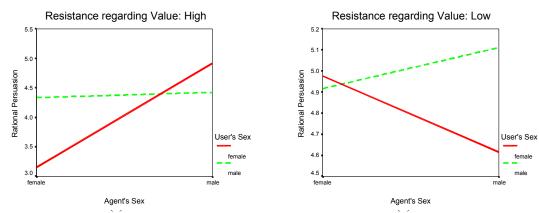
Figure 7(a) indicated that, at high level of resistance regarding value, gender of the change agents did not differ significantly in their use of assertiveness tactic with female users. Both showed lesser tendency to use assertiveness with their female users. However, in influencing male user, female change agents exerted more assertiveness, as compared to male change agents. When resistance regarding value is low [see Figure 7(b)], both male and female change agents showed same extent and greater tendency to use assertiveness tactic with their female users. However, male change agents, as compared to female change agents, made frequent use of assertiveness tactic with their male users at low level of resistance regarding value. Figure 8(a) revealed that, at high level of resistance regarding value, change agents showed greater tendency to use reminding tactic with users of the opposite sex. However, when resistance regarding value is low [see Figure 8(b)], both male and female change agents did not differ in terms their use of reminding with their male user. However, male users at low level of resistance were significantly higher influenced with reminding, as compared to female users.


Figure 5: Interaction among Resistance regarding Value, User's Sex, and Change Agent's Sex on Rational Persuasion.

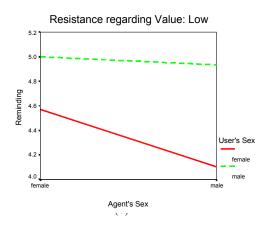

Figure 8: Interaction among Resistance regarding Value, User's Sex, and Change Agent's Sex on Reminding.

DISCUSSION AND CONCLUSION

Change agents play a critical role in implementing new technology or information in an organization. In order to gain the compliance from users, they spend time to convince and influence others to commit to strategic technology initiatives (Lederer & Mendelow, 1988). Therefore, a throughout understanding of the effective use of influence tactics is important for change agents' right choice during their influencing process.

In this study, personalized exchange comprised of items from soft tactics, (e.g., exchange, personalized help, and instrumental dependency), which is the least used influence tactics among the six tactics by change agents in Malaysia (M=3.48; SD=1.08). To the contrary, rational persuasion is the most used tactic by change agents to influence users (M=4.54, SD=1.08). Findings are consistency with previous study, which claimed that change agents with greater technical background used rational persuasion almost exclusively and it is believed that change agents, especially for those work as the internal IT specialists, who often possess technical backgrounds may be reluctant to engage in soft influence tactics (Enns et al., 2003).

This study articulates a framework to understand the relationship among user's level of resistance, gender differences, and the effective use of influence tactic by change agents. Therefore, it would add to the limited literature in understanding the antecedents of the use of influence tactic. On the other hand, this study also has some practical implications for change agents. It explores the simple dispositional relationship between user's level of resistance and influence tactics. There is no single best influence tactics for all situations. Change agents should not employ one particular tactic to all users, on the contrary, they have to diagnose various users' level of resistance and select the best-fit tactic to convince their users during the implementation of the new technology.

Additionally, the present study classified the user's level of resistance into four dimensions, and it was found that appropriateness of a single tactic is differently related to various dimension of resistance level. For example, hard tactic (e.g., upward appeal and reminding) is effective to be used when confronting with user's high level of resistance regarding timing, to the contrast, it was less effective at high level of resistance regarding overall set up and value.

While men may still represent a majority of the workforce, particularly in technology-oriented areas, the number of women in these areas and all levels of the organizational hierarchy continue to rise (Venkatesh et al., 2000). The present study brings findings to the forefront by showing the impact of gender differences on the effective use of influence tactics. A more substantive implication of this study is its exploration of the interactive effect of gender differences and level of resistance. Besides that, the study examined both gender of the user and the change agent as the interactive predictor of the change agents' use of influence tactics. Soft tactics is effective to be used by the change agents with users of their own sex. Overall, the findings of the study indicate that the use of influence tactics is affected by gender difference and level of resistance. Therefore, change agents should take into account of gender differences (i.e., user's sex and change agent's sex) during their influencing process with users who possess different level of resistance.

Results of the study suggest that in responding to high level of resistance, female change agents, as compared to male change agents, showed a distinctive tendency to use expert help, assertiveness, and reminding to their male

users. To the contrary, male change agents significantly reported the higher use of rational persuasion, upward appeal, and reminding to their female users at high level of resistance.

Strength of this study is by using users' assessments of the actual effective use of change agent's influence tactics instead of their perceived exercise of influence tactics that is prefer by the target. Adhere to Carli (1999) suggestions, evidence for gender differences in influence strategy is ideally included observations of actual behavior. Besides that, it lessened the risk of the change agent's self-report bias in the data.

There are numbers of limitations in this study. Due to the time constraint, the samples were collected from individual (users) located in Penang. Findings based on self-reports are somewhat limited in respondents' utility because they may not report their behavior accurately (Carli, 1999). Therefore, it is more profitable if the data were collected in dyadic evaluation, that is, survey regarding user's level of resistance to be reported by change agent, whilst survey regarding change's agents actual use of influence tactics to be evaluated by users.

With the growing presence of women in the workforce at all levels, the study suggests that the use of influence tactics is affected by gender differences. The gender of the users and change agents found to have little independent effect on the use of influence tactics. However, gender interactive effects with level of resistance appear to change the use of influence tactic by change agents. Therefore, future researchers should treat gender of users and change agents as the moderator variable.

As a conclusion, this research suggests that, change agents differ their use of influence tactics according to resistance level of the user. Findings reveal that change agents adopt different influence tactics in responding to the user's level of resistance. Besides that, men and women change agents differ in the use of influence tactics. Additionally, they vary their use of influence tactic according to the gender differences of the user. As a result, change agents must understand the factor of user's resistance level and gender differences that are likely to lead to their effective use of influence tactics. In the end, change agents who are responsible for the strategic technology initiatives must improve their skills to read and diagnose user's different level of resistance in order to select the best-fit tactic during their influencing process.

An Analysis of the Strategic Planning Process:
Traditional Approaches and New Perspectives

Kartinah Ayupp

ABSTRACT

Strategic planning and analysis tools have been the subject of much scholastic debate over the last 20 years. A strategy is the vital foundation that holds a business together. Strategies give direction to the organization, determine its structure, the activities engaged, resources deployed and ultimately, its organizational performance. Given the importance and complexity of this activity, one would expect to find a literature in which there is a general agreement as to its significant characteristics and dimensions. Such is not the case. Thus, this paper aims to provide an overview of major work that has been carried out in this area and also highlight the divergence between the numerous schools of thoughts. The assimilation of these perspectives and viewpoints should enhance the reader's understanding of what strategic planning is and is not, thereby contributing to higher levels of awareness on why one approach is inadequate for the task of managing an organization in today's complex business environment.

INTRODUCTION

Although application of the concept of strategy has been part of management literature since the 1950s, there are still vastly conflicting views regarding its role and also, appropriate approach. Among the most important work in the early development of the field of strategic management are Chandler's (1962) Strategy and Structure, and Ansoff's (1965) Corporate Strategy. These early works centered on the use of objective and highly systematic procedures in strategic planning process, where strategists identify, evaluate, choose and carry out effective strategic options based on logic and extensive knowledge of important factors.

Recent developments in strategic planning literature have seen an increasing number of approaches that have given rise to conflicting views on the subject. For example, in *Strategy Safari,* Minzberg, Ahlstrand and Lampel (1998) list a total of 10 ways in which strategy is developed, while Whittington in his book *What is Strategy and Does it Matter?* (Whittington, 1993) categorizes strategic planning under four primary approaches, namely:

Classical approach
The classical approach views people and organizations as rational economic actors, assumed to respond in ways designed to optimize economic rewards. It emphasizes top-down management and profit maximization as the unifying goal in its strategic planning. Among the early proponents of this approach are Alfred Chandler (1962), Igor Ansoff (1965), and Alfred Sloan (1962). This strategy was historically derived from two type of models; the military concept of hierarchical command where a leader is regarded as the decision maker of all strategies, and the economic theory of rational optimization where profit maximization is considered as the ultimate goal of an organization.

Evolutionary approach
This 'survival of the fittest' principle is taken from the premise that the market forces determine the winners and losers in the business environment. Thus, evolutionists are against trying to outguess the market by investing heavily in a single major plan, but rather to only concentrate on short-term plans and fitting in with the market. With its emphasis on organizations to maintain high efficiency, evolutionary theory is regarded as a subset of a wider class of theories, variously described as 'capabilities', 'resource-based' or 'competence-based'. The central idea of competencies provides the basis for evolutionary and non-equilibrium theories of industrial competition and development. Among the early proponents of this theories are Adam Smith and Karl Marx; while the twentieth-century advocates include Chandler (1990), Hamel and Prahalad (1994), Pettigrew and Whip (1991).

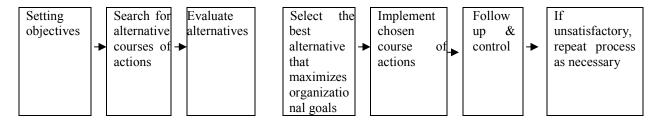
The processual approach

This approach differ from both classical and evolution in the sense that strategy is viewed as more of a "muddling through" of small incremental steps. This involved repeated adjustments and compromise between the different stakeholders of the organization. The concept of the rational economic man making all the appropriate strategies (as advocated by the classics) and evolutionists' view of the market as the perfect force are deemed erroneous by these theorists. As put forward by Cyert and March (1963), people do not carry out unlimited search for information when doing strategic planning. They are often biased in their interpretation of data and accept the first satisfactory option that come to hand rather than finding the best one. Furthermore, because an organization is made up of different coalitions of individuals, strategic planning involved a lot of political and social skills to modify and gather support for strategies.

Systemic approach

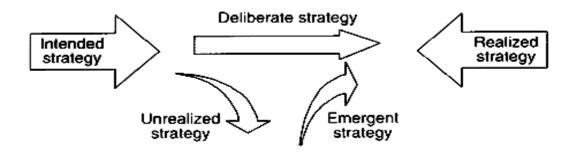
Systemic theorists believe that in order to be successful a strategy must adapt and take into accord the social systems that the organization is operating in. Different value and assumptions regarding the environment will lead to managers taking into account different range of issues when considering strategies. This aspect is especially important when operating in an environment that places high importance on familial, national value and work structure (Ali, 1993, Al-Jafary & Hollingsworth, 1983; Chow, 1992; Dunbar & Katcher, 1990; Fukuyama, 1995; Gilley, 2000, Mintzberg, 1994, Selmer and de Leon, 1993).

As can be seen from the above, there are at least four major categorizations of strategic planning, as schools of thought. However, there are also similarities in certain aspects of the approaches/theories that make the differences not as huge as individual labels may presume. To a large extent, the argument about strategic planning methods lies between two broad approaches: the 'planning' school that regard strategic planning as a systematic, clear and articulated process; and the 'emergent/learning' school that views planning as an adaptive process arising from the organization's experience, culture and ever-changing environment. However, even these differences can be viewed as complementing each other when specifics are looked at. This can be seen from the growing body of empirical literatures that regards these categorizations of strategic planning as 'academic overkill' and suggests that in a complex business environment, both the planning and adaptive mode have a complementary rather than opposing role in ensuring effective decision-making. One such view comes from De Wit and Meyer (1999) who acknowledged that there is no one best way to formulate strategy, but rather, strategists need to integrate ideas from different thinkers to shape a unique synthesis that is tailored to their specific circumstances. This line of thought is echoed by Raymond Suutari (1999), who noted that in virtually every circumstance, the strategic decisions should be based on the combination of both the planned processes that examine the firm's position systematically; and also the "adaptive mode" process that reconciles the planned action with organizational capabilities, constraints and culture.

STRATEGY MODELS


Although there is no single best way to organize a firm or formulate a strategy, there are always some approaches that are more effective than others. As put forward by Hoy and Miskel (1991), the "best approach" is one that fits the circumstances. So it is not surprising to see the different types of planning formulation/decision-making models, in line with the changing dynamic of the business environment. For instance, Tarter and Hoy (1998), based on his study on a contingency theory of decision-making, use a series of seven criteria to compare the similarities and differences among the six contemporary decision-making models:

Table 1: Comparison of Decision-Making Models

Models \ Criteria	Classical	Administrative	Mixed Scanning	Incremental	Garbage Can	Political
Setting Goals	Organizational objectives are set prior to alternatives	Objectives usually are set prior to alternatives	Policy guidelines are set prior to alternatives	Objectives & alternatives are intertwined	Objectives emerge spontaneously	Objectives emerge spontaneously
Means-end analysis	Always begins with a means-ends analysis	Frequently begins with a means-ends analysis, but occasionally ends change	Broad ends & tentative means focus the analysis	No means-ends analysis. Means & ends are not separable	Means & ends are independent; chance connects them	Personal ends determine organizational means
Test of a good decision	The best means to an organizational end	A satisfactory organizational outcome	A satisfactory organizational outcome	Decision makers agree that the decisions are in the right direction	Participants agree that the solution & problem match	Personal objectives are accomplished
Guiding principles	Theory	Theory & experience	Theory, experience & comparison	Experience & comparison	Chance	Power


Sources: Tarter, C John; Hoy, Wayne K, Toward a contingency theory of decision making, Journal of Educational Administration; Volume 36 No. 3; 1998.

The strategic planning approach has been reflected in large part of the literature as a rather centralized process. The rational decision making model conceives strategic planning processes as logical activities that allow management to analytically determine an appropriate strategic path for their organization. This model which is also known as the "design school" or "fit school" relies on the premise that the goal of a strategy is to find a match between organization capabilities and opportunities within the competitive environment. This model is advocated by numerous authors such as Harrison and Pelletier, 1998, Johnson and Scholes, 2000, Ohmae, 1983; Wheelen and Hunger, 2004, David, 2003, Andersen, 2000).

| Setting objectives | → | Search for alternative courses of actions | → | Evaluate alternatives | | Select the best alternative that maximizes organizational goals | → | Implement chosen course of actions | → | Follow up & control | → | If unsatisfactory, repeat process as necessary |

Mintzberg was one of the first to highlight the fact that the result of an organization's strategy is not always the intended one, and the extent that an intended strategy can be realized is dependent on the strategic processes that exist within that organization. This is illustrated in the figure below:

Figure 1: Intended vs. Realized Strategy

In the concept of strategic 'stretch', strategic planning is seen not only as trying to ensure that resources are available, but also use to identify existing resources and competences that might be a basis for creating new opportunities (Harding, 1994). Strategies are normally formulated to cover three levels in an organization; corporate level, business level and operational level strategies.

Within these strategies' levels, management needs to determine the right mix of control and cooperation mechanism to ensure synergy. This is done by making sure that there is a right balance between the need for responsiveness in meeting environmental changes, and the need for synergy among the business units. This paradox of responsiveness and synergy leads to differing opinion on how to achieve these objectives; with debates going on between two main opposite views - the *portfolio* versus the *core competence* perspective. The differences between these two perspectives could be seen in the table below, taken from the book by De Wit and Meyer, the *Strategy Synthesis: Resolving Strategy Paradoxes To Create Competitive Advantage* (1999):

Table 2: Portfolio Versus Core Competence Perspective

	Portfolio Perspective	Core Competence Perspective
Emphasis on	Responsiveness over synergy	Synergy over responsiveness
View of competition	Firms compete within a business	Corporations compete across businesses
Competitive strategy at	Business level	Corporate level
Key success factor	Responsiveness to business demands	Competence leveraging
Corporate composition	Potentially unrelated (diverse)	Shared competence-based (focused)
Multibusiness synergy	Cash flow optimization	Rapid competence building
Primary task corporate center	Capital allocation to SBUs	Competence development & application
Position of business units	Highly autonomous (independent)	Highly integrated (interdependent)
Coordination between SBUs	Low, incidental	High, structural
Corporate control style	Setting financial objectives	Joint strategy development
Diversification acquisitions	Simple to accommodate	Difficult to integrate

Proponent of the core competence perspective such as C.K Prahalad and Gary Hamel (1994) use the Japanese business environment as an example to illustrate how tight coordination and cooperation mechanisms are the best way to cash in on market opportunities. According to them, the real source of advantage is in management's ability to consolidate corporate-wide technologies and skills into competencies, so that individual businesses can pursue a wider domain of innovation rather than pursuing 'bounded' innovation opportunities - such as marginal product-line extensions or geographic expansions. On the other hand, proponents of the portfolio perspective view core

competence approach as not only leading to loss of responsiveness, but ultimately lack of accountability and 'fuzzy' cooperation. This is borne out by many authors (such as Henderson 1979; Anslinger and Copeland, 1996), who pointed out that each business has its own unique characteristics and demand, and high responsiveness to the dynamic business environment could only be achieved through autonomous business.

STRATEGIC ANALYSIS TOOLS

In the 1960s, long-range planning was mostly concentrated on functional aspects within the firm, making sure of effective alignment of each function – marketing, production, finance, and human resources to achieve organizational goals. Although this planning process was appropriate for the relatively slow-paced environment of that era, the emerging high-growth business environment in the 1970s and 1980s made it essential for managers to seek new methods of strategizing. The current environment of dynamic interaction and fast changes make external as well as internal focus equally important, with the major focus in strategizing turning increasingly towards both customers and competitors.

Changes in the form of strategic analysis tools have been documented by numerous researchers in the fields. Among the more important tools identified during the past several years are:

SWOT Analysis (1960s):
Analysis at the firm level of strengths, weaknesses, opportunities and threats. This framework can help firms to search for their distinctive competences and assess their competitive positioning through organization-environment fit, that is, matching a firm's strengths and weaknesses to its opportunities and threats. Among the researchers that have been involved in this area are Ansoff, 1965; Andrew, 1971; and Hofer and Schendel, 1978.

BCG Growth-Share Matrix (1970s):
This framework was developed by the Boston Consulting Group, and is mainly concerned with the pattern of the firms' investments in different products. Classification of activities was based on two indices; the industry's rate of growth, and the relative market share of the firm in question. The assumption is that, if the firm is operating in a high growth industry, then it is easier for the firm to expand its activities by increasing its relative market shares, and secondly, the higher a firm's relative market share, the stronger its competitive position is assumed to be.

Another portfolio analysis that used a two-dimensional grid (in this case, market growth and relative market share) to classify the different businesses is the GE Matrix. This framework was developed by General Electric and McKinsey.

Profit Impact of Market Strategy Analysis (1970s and Early 1980s):
The PIMS approach was developed at Harvard Business School and is another type of portfolio analysis framework. Its aim is to study factors that influence profitability in a business and the degree of influence that each of these factors has. It was established to address certain limitations of BCG and GE models, i.e., more in-depth analysis of other factors that relate to profitability and ROI, and not just concentrating on market share/relative market share. This portfolio analysis model investigates additional factors such as investment intensity, value added per employee, capacity utilization, vertical integration, industry concentration, etc.

Industry Analysis – Five Forces (early 80s):
Industry analysis was introduced by Michael Porter as a means of identifying the forces that shape the nature of the competitive environment. Five factors were cited as the determinants of competitive intensity in an industry, namely; barriers to entry, barriers to substitutes, rivalry intensity, bargaining power of suppliers and buyers. The framework works on the premise that firms operating within an industry possess identical resource bases and pursue similar strategies. Although it was quite a popular concept when first introduced, over the years it has been heavily criticized, among other things, for being descriptive, rather than prescriptive – providing little guide to what firms should actually do, or avoid doing. As put by critics, every firm would like to be in an industry with high barriers to entry, weak rivals and high profits, but few are so lucky.

Value Chain Analysis (mid 80s):
Porter (1985) recommend value chain as a means to identify and study those business activities that could transform inputs into rent-generating potential. According to him, "Difference among competitor's value chains are a key source of competitive advantage." Corporate value chain analysis involves examining:
- Each product line's value chain in terms of the various activities involved in producing that product or service

- The 'linkages' within each product line's value chain. Linkages are the connections between the way one value activity (e.g., production) is performed and the cost of performance of another activity (e.g., QC).
- The potential synergies among the value chains of different product lines or strategic business units.

Scenario Analysis (1970s, 1980s):
It is used by decision-makers in business, industry and government as a technique for analyzing a set of possibilities and exploring these combinations so as to improve current decisions. According to Fahey and Randall (1988), the purpose of scenario building is to:
- Enhance understanding of how the future might look, including the reasons why each particular view of a possible future might come about,
- Encourage diverse and new decisions by bringing into consideration fresh approaches in the planning process,
- Identify contingent decisions by investigating what an organization might do if certain circumstances arise.

They also categorize the scenarios into three dimensions, namely:
- Global scenarios: several distinctive future environments are selected in order to see the different implications for long-term ventures, investments and operating decisions.
- Industry projects: it projects how the current industry might evolve and what the organization can do to remain competitive and/or be a leader in this industrial future.
- Competitor scenarios: it tries to identify and analyze possible strategies that competitors might adopt in various circumstances.
- Technology scenarios: developed a better understanding of opportunities and risks in this scenario dimensions so that the organization can make better technological decisions.

Economic Value Added (EVA) (1990s):
The New York consulting firm Stein introduced and popularized the two shareholder value measures: EVA and Market Value Added (MVA). Given the limitations of previous accounting measures, several well-known firms (such as Coca-Cola, General Electric, AT&T, Whirlpool, Quaker, etc) began adopting EVA methods for evaluating their performance. As asserted by authors such as Wheelen and Hunger, 2002; Stern et al, 1995; Tully 1993; EVA has become an extremely popular shareholder value method of measuring corporate and divisional performance and may be on its way to replacing ROI as the standard performance measure.

Managers can improve their firm's or business unit's EVA by [1] earning more profit without using more capital, [2] using less capital and earning the same level of profit, and [3] investing capital in high-return projects. In their article " The Domain of Strategic Management: History and Evolution", Bowman, Singh and Thomas (2002) explains it concisely by putting the pro and cons of the EVA method:

> *By measuring the value added over all cost, including the cost of capital, EVA measures the productivity of all factors of production. It does not, by itself, tell a decision maker why a certain product or a certain services does not add value, or shed light on courses of action to recover value.*

Capacity Analysis (1990s and currently):
With the need to achieve consistency between the firm's resources and its strategy, its not surprising that waves of new approaches which are inwardly-focused are becoming more popular. Concepts such as Total Quality Management, reengineering, experience curve, and the learning organization delve into the internal analysis of activities within organizations. The need for a more holistic view of strategic thinking eventually gave rise to the popularity of RBV theory. This theory helps to bridge the gap by focusing on the relationship between internal analysis of the firm with external analysis of the industry and competitive environment. According to the RBV theory, a resource that is valuable in a particular industry and/or time, might not be valuable in a different industry or at a different time. The rate and direction of an organization's growth is influenced by how effectively management utilizes and develops its resource base; which in turn influences management decisions on the organization's feasible expansion paths, and the strategies it chooses to pursue (Grant, 1991; Peteraf, 1993).

However, these authors caution strategists to be objective when evaluating the value of their organization's resources. Failure to do so might cause strategies to fail. As stressed by Collins and Montgomery (1995), in order for a resource to qualify as a basis for effective strategy, it must pass a number of external market tests of its value. The tests are:

- ***Test of inimitability: Is the resource hard to copy?*** If a resource is inimitable, then the profit generated from it is likely to be more sustainable. Although competitors will eventually find ways to copy these resources, managers can forestall them by building their strategies around resources that have at least one of the following characteristics: [i] physical uniqueness, [ii] path dependency, and [iii] causal ambiguity.
- ***Test of durability: How quickly does this resource depreciate?*** The longer lasting a resource is, the more valuable it will be. Like inimitability, this test asks whether the resource can sustain competitive advantage over time.
- ***The test of appropriability: Who captures the value that the resource creates?*** Not all profits from a resource automatically flow to the company that 'owns' the resource. Basing a strategy on resources that are not inextricably bound by the company can lead to difficulty in achieving profits.
- ***The test of substitutability: Can a unique resource be trumped by a different resource?*** This test considers whether the organization have resources that can be substituted by competitors.
- ***The test of competitive superiority. Whose resource is really better?*** This test assesses the resources relative to competitor's in order to ensure that the company is able to exploit opportunities and/or neutralize threats in the competitive environment.

Another theoretical perspective that is closely related to the RBV is that of competence-based theory. Among the advocates of this theory are Sanchez, Heene and Thomas, 1996; Prahalad and Hamel, 1994; Stalk, Evans and Schulman, 1992. Prahalad and Hamel in their book *Competing for the Future* (1994), suggest that rather than behaving reactively, successful firms in the future strive not only to shape their existing competitive space, but to create new competitive spaces for themselves as well. According to them:

> *Companies that see strategy as primarily a positioning exercise are industry rule-takers rather than rule-breakers and rule-makers; they are unlikely to be defining entity in their industry, now or ever.*

In short, strategy is as much about competing for tomorrow's industry structure as it is about competing <u>within</u> today's industry structure. Competition within today's industry structure raises issues such as: What new features should be added to a product? How can we get better channel coverage? Should we price for maximum market share or maximum profits? Competition for tomorrow's industry structure raises deeper questions such as: Whose product concepts will ultimately win out? Which standards and product concepts will ultimately win out? Which standards will be adopted? How will coalitions form and what will determine each member's share of the power? And most critically, how do we increase our ability to influence the emerging shape of a nascent industry?"

COGNITIVE-BASED APPROACH TO STRATEGIC PLANNINNG

The cognitive-based approach to strategic planning has proved to be a significant approach for studying the strategic planning process. This is because the process involves not only the rational planned approach but also the use of intuitive judgment, influenced by the strategists' experience, culture belief, and value systems. Empirical research highlighted that among the positive aspects of intuition are that it can accelerate strategic decision-making and can serve as a substitute for procedural comprehensiveness or formalization of strategic planning (Mitchell and Thompson, 1994).

Political issues, and also differing interpretation and perceptions of the organization's strengths, weaknesses, opportunities and threats are also some of the cognitive-based factors that influence strategic planning process. More often than not, strategy is a compromise between planned intent, and the cultural and organizational constraints of the organization (Harrison, 1987).

With this in mind, understanding the composition of one's stakeholders is important, because it enables the strategists to assess the organization's adaptive capacity, its point of resistance, and its blind spots (Eden and Spender, 1998). Stakeholder priorities, dominant CEOs and corporate culture can create resistance to change, or result in strategies going through the hurdle of a difficult planning process which saw them being significantly changed to facilitate implementation. Johnson & Scholes (1999) acknowledge this phenomenon by stating that strategy development is the outcome of cultural and political processes. They define organizational culture as a *''deeper level of basic assumptions and beliefs that are shared by members of an organization, that operate unconsciously and define in a basic taken-for-granted fashion an organization's view of itself and its environment'*. According to them, these well-established beliefs are usually rooted in past experiences; while the political aspect

can mean stakeholders' influence leading to processes of bargaining, negotiation or perhaps edict to satisfy the different interest groups' expectations and priorities.

One school of though that delves into this concept of conflicting goals is that of Agency Theory. It posits that due to the split of ownership and control in organizations, there is usually a conflict in priorities between shareholders (principals) and managers (agents). This theory assumes that people are opportunistic and are bounded rationally, and therefore, managers will try to fulfill their own interests even at the expense of the shareholders. Meanwhile, research studies done by authors such as Hofstede 1993, Whittington 1992, and Mead 1994, have examined how the process of interpreting strategic issues may also be influenced by national culture and work systems. They pointed out that these differences would be expected to influence the degree of centralization, formalization, and political behavior both in gathering data on strategic issues, and the actual strategic planning process. For example, it may result in either a top-down formal strategic planning model, or a more informal 'adaptive' model.

There are also numerous other approaches to the study of cognitive processes such as cognitive psychology, decision processes, sociology of knowledge, etc. Although there seems to be consensus among researchers in regard to the conflicting priorities experienced by stakeholders in an organization; there tends to be differing views on how this conflict actually affects the organizational planning process. While some argue that conflict hinders effectiveness, other newer researches show that they can actually improve the decision quality. Eisenhardt (1999), based on her study of about twelve European, Asian and North American multi-business firms, concludes that the most effective strategists made choices that were fast, high quality, and widely supported. This is done by:

- Building collective intuition through frequent meetings and real-time metrics that enhance the ability of a top-management team to see threats and opportunities sooner and more accurately.
- Stimulating quick conflict to improve the quality of strategic thinking without sacrificing significant time.
- Maintaining a disciplined pace through time pacing, prototyping, and consensus that drives the decision process to a timely conclusion.
- Defusing political behavior that creates unproductive conflict and wastes time by emphasizing common goals and clear area of responsibility, and having fun.

According to Eisenhardt, rather than avoid conflict, high-stake decision-making needs divergent views among managers to stimulate innovative thinking, create fuller understanding of options, and improve decision effectiveness. She highlighted the methods that could be used to accelerate conflict, including assembling executive teams that are varied in age, gender, functional background and corporate experience; using "frame-breaking techniques"; and applying multiple alternatives through scenarios creations.

In addition to the above, another important element in cognitive-based research is the role of leadership in the planning process. For instance, research undertaken by Nutt, (1993) indicates that powerful decision makers often impose their ideas on a decision process, and although this creates a clarity of purpose, more often than not, this clarity could be misleading because it can sweep aside some of the sources of ambiguity and uncertainty.

Hence, there is a wide scope in the study of cognitive-based explanations of strategic planning and this aspect is being acknowledged by many authors such as Stubbart, Meindl and Porac (1994). According to them, although there are various cognitive theories that share much in common, they diverge around four central concepts, that are: rationality, the role of "mindless" or rote behavior, intended behavior, and whether cognitions are restricted to actions to be taken or include values and norms:

- *Mindlessness:* According to the new institutionalists, organizational members sometimes do habitual activities because they believe that "that is the way these things are done'. The theorists see this as mindless because the behaviors are brought into the organization not because they are rational, but because they are viewed as appropriate by external society. The counter arguments by other cognitive researchers state that rather than being routinized actions, this behavior is normally rooted because of past successes and is also important in order to increase efficiency in human decision making and actions (e.g., consistent decisions, or predictable action).

- *Rationality:* Traditional organization theorists have always defined rationality from the management perspective - in terms of organizational, economic and managerial viewpoints. Whereas more recently, both social scientists and managers have began to view it from a wider angle - as that from the actor's perspective, which govern perception, interpretation and action. Thus, the actor's desired outcomes and the actor's belief in the connection between intended action and desired outcome is what constitute rationality in this approach.

- ***Intended purpose:*** The "new institutionalists" view any behaviors adopted by an organization due to external environmental pressures/influence as being "without purpose". While another quarter note that behaviors and values taken from the society that enable the organization to get resources and avoid penalties are serving the intended purpose pursued by the organization.

- ***Maintenance activities:*** Maintenance activities are seen as important by some cognitive-based researchers because they help in preserving the organization's legitimacy in the larger society - such as insuring ethical behavior, preserving values, social responsibility, etc. Others view the maintenance activities as more about ensuring new pattern or dynamic changes that organizations need to make to face environmental conditions that may threaten the organizational survival.

SUMMARY

Notwithstanding the above views, academics and practitioners generally agree that the goal of the strategic planner is to build sustainable and profitable competitive advantage. Although there are many definitions of strategic planning, certain points stand out:

- It is likely to be concerned with the full scope of the organization's activities.
- It involves the matching of the activities of the organization to its resource capability and the environment in which it operates.
- It involves a significant commitment of resources.
- It involves a longer-term perspective

With this in mind, an organization's ability to strengthen its position is dependent on its ability to consistently make the optimal strategic choices. To achieve this, strategy involves making tough choices on three dimensions: which customers to focus on, which products/services to offer, and which activities to perform. Making the correct decisions on these three aspects is crucial because organizations sometimes make the mistake of entering businesses based on similarities of products rather than on the resources that contribute to the competitive advantages in each business. As emphasized by Collins and Montgomery in their article *Creating Corporate Advantage* (1998), as brilliant as any one strategy might be before its intended organization, it would not necessarily work well for all companies. This is because every organization starts at a different point, operates in a different context, and has fundamentally different kinds of resources and objectives.

ABSTRACT

Past researches in the literatures on manager-employee attitudinal congruence have generally found that attitude similarities between managers and employees are linked positively to job-related outcomes. This research attempts to analyze the relationship between leader-member exchange (LMX) and Organizational Citizenship Behavior (OCB) among executives employed in East Malaysian manufacturing organizations. Moderating the above variables is the gender of the supervisors and subordinates. The findings suggested that LMX has significant implication on citizenship behaviors performed by subordinates. It was also noted that, gender dissimilarity was found to moderate the relationship between LMX and OCB resulting in subordinates reluctance to perform citizenship behaviors.

INTRODUCTION

Management behavior is an important area of study as it can provide assistances or guidelines to the management on the appropriate method of developing the most effective workforce. Lord and Brown (2001) found that leadership works best when there is a match between the identity level of followers and the focus of leaders, as people of similar behavior tend to be attracted to each other. Past researches in the literature on manager-employee attitudinal congruence have generally found that attitude similarities between managers and employees are linked positively to job-related outcomes. Supervisor-subordinate interactions and unequal power distributions are some pervasive features of modern organizations. Having said that, a better understanding of these effects will offer insights into positively influencing employees' behavior. The major concern of organizations nowadays is establishing effective leadership management and the core element in developing effective leadership management is the quality level of exchange relationship between superiors and subordinates.

The leader-member exchange (LMX) and Organizational Citizenship Behavior (OCB) have become the foundation of a new era of managing a diversified workforce in the advent of globalize world. Sarawak, a state located in East Malaysia, has gone through rapid transformation from primary sector such as agriculture and mining to a highly skilled manufacturing sector in the 1990s. Thus, understanding the relationship between supervisors and subordinates would serve as a platform for supervisors to assist them in develop an OCB culture among their subordinates through favorable LMX or social exchange relationship between superiors and their subordinates.

The major objective of this particular research is to promote awareness among the superiors with regards to the importance of understanding and practicing LMX as an effective medium interaction between superiors and subordinates as well as fostering OCB among subordinates.

The major concern of this research is to determine whether the LMX theory and OCB are applicable in the manufacturing companies located in Sarawak. This research attempts to answer the following questions:

- How would the Leader-Member Exchange (LMX) affect the Organizational Citizenship Behavior (OCB) among the employees?
- How would the gender of supervisors and subordinates moderate the relationship between LMX and OCB?

LEADER-MEMBER EXCHANGE (LMX)

LMX theory was first illustrated in the works of Dansereau, Graen, and Haga (1975) 29 years ago and has recently been gaining momentum. Many studies have been conducted to investigate the role the supervisor plays in his or her relationship with subordinates. Essentially, the supervisor, the subordinate, or both will evaluate the relationship according to the quality of the interaction and these perceptions have a fundamental influence on individual outcomes. As mentioned by Murry, Sivasubramaniam, and Jacques (2001), the positive exchanges are typically reciprocated with positive outcomes from the subordinates. Each member of the dyad has the other's best interest at heart and this is reflected in more supportive behavior.

LMX describes the relationship between a leader and a subordinate and how they influence each other in an organization and examined their interdependencies (Yukl, 1998; Scandura, 1999). Early works in LMX have found two types of relationships between the subordinate and supervisor, namely the in-group and the out-group. In-group refers to linkages based on expanded and negotiated role responsibilities, which are not specified in the employment contract and conversely out-group is based on the formal employment contract. Subordinates in the in-group are claimed to have more power as they receive more information, are more influential and confident, and have personal concern from their leaders as compared to the out-group subordinates (Liden, Wayne, & Sparrowe, 2000). In-group members are willing to do extra tasks and to which their leaders will reciprocate (Graen & Scandura, 1987) but out-group members receive lesser attention and support from their leaders and thus might see their supervisors as treating them unfairly.

Many literatures in the past have revealed that supervisors do differentiate between their subordinates in terms of the exchange. It is an advantage to be in a high LMX as it is associated with higher trust, greater warmth and support, and there is more frequent interaction between the members of the dyad (Dansereau et al., 1975; Brower, Schoorman, & Tan, 2000). Most current LMX researches depart from previous LMX research by looking into other analysis as long as the relationship remains the focus. Recently, LMX has been related to behaviors such as organizational citizenship behaviors (Settoon, Bennett, & Liden, 1996; Wayne, Liden, Graf, & Ferris, 1997; Deluga, 1998; Hui, Law, & Chen, 1999), task performance (Howell & Hall-Merenda, 1999; Hui et al., 1999; Settoon et al., 1996; Wayne et al., 1997), turnover intentions (Ansari, Daisy, & Aafaqi, 2000), managerial roles congruence (Lim, 2001), organizational outcome (Omar, 2001), conflict handling style (Oh, 2002), and influence tactics (Liew, 2003).

LMX literatures had found that subordinates in high-quality exchange relationships received more desirable assignments, more rewards, and had greater support from their supervisors. This is congruent with the social exchange theory, where individuals who are engaged in high-quality relationship will behave in such a way that their exchange partner will also get the benefits (Murphy, Wayne, Liden, & Erdogan, 2003).

ORGANIZATIONAL CITIZENSHIP BEHAVIORS (OCB)

Organizational citizenship behaviors or as it is also known as extra-role behaviors, are the act of performing beyond the stated job requirement. Subordinates impulsively go beyond the employment contract and carry out non-obligatory task without expecting explicit rewards and recognition (Organ, 1988).

In addition to that, citizenship behaviors can be explained based on the psychological contract between employees and organizations, where the core element in the contract is reciprocity obligations between employees and organizations (Masterson & Stamper, 2003; Thomas, Au, & Ravlin, 2003). Organizations have the obligation in terms of providing to employees benefits, such as career advancement, promotions, job security, training, and increased salary. In return, the employees' responsibility to the organization will include loyalty, helping colleagues, willing to work overtime, and accept tasks that are beyond normal job requirement.

In summary, OCB is the extra-role behavior exhibit by employees, which go beyond the formal job requirement without expecting recognition in term of either explicit or implicit rewards from the supervisors. The effect of OCB is more likely to promote positive social and working environment while maintaining the performance of a work unit relative to the core products of the organizations.

Five Dimensions of Organizational Citizenship Behaviors

OCB can be classified into five categories that contribute to organizational effectiveness which include altruism (helping), courtesy, conscientiousness, civic virtue, and sportsmanship (Organ, 1988). Smith, Organ, and Near (1983) defined altruism as voluntary behaviors where an employee provides assistance to an individual with a particular problem in completing his/her task under unusual circumstances. Courtesy includes behaviors, which focus on the prevention of problems and taking the necessary step so as to lessen the effects of the problem in

the future. Organ (1988) defined sportsmanship as the behaviors of warmly tolerating the irritations that are an unavoidable part of nearly every organizational setting. According to Deluga (1998), civic virtue includes subordinate participation in organization political life and supporting the administrative function of the organization. Meanwhile, conscientiousness is considered as one of the personalities of the "Big Five Dimensions of Personality," which is used to indicate that a particular individual who is organized, accountable and hardworking. Besides that, studies have also revealed that conscientiousness can be related to organizational politics among employees (McCrae & Costa, 1987).

The Impact of Organizational Citizenship Behaviors on Organizational Effectiveness

Prior studies had disclosed that OCB has significant implication on the organizations' output. In a research conducted by Podsakoff, Ahearne, and Mackenzie (1997), they found that there is a positive correlation between OCB and an organization's outcomes. This is due to OCB being able to foster the effectiveness of organizations in terms of achieving a higher level of work group performance from the perspective of quantity and quality of work. According to Aquino and Bommer (2003), they discovered that OCB can enhance the social attractiveness in a work unit. As OCB is normally labeled as positive behaviors, those who exhibit OCB may become more socially attractive which makes them more likely to be appreciated as friends or partners. Consequently, this may create a favorable working environment in a work unit.

GENDER

According to Wayne, Liden, and Sparrowe (1994), there are two approaches of gender effect on LMX, which is known as similarity-attraction approach revealed by Byrne (1971). The approach conceptualized that similarity between leader and member may lead to increase liking and thus influence their exchange relationship. Meanwhile, the other approach which is known as situational approach is related to proving that situational variables such as formal authority, experience and influence may affect the gender effect in developing exchange relationship between leader and member.

According to Xin and Pelled (2003), role conflict may arise from task conflict and emotional conflict that may leave significant impact on the social exchange between superiors and subordinates. Therefore, the outcome of their study indicated that female leaders with female members develop a favorable relationship in term of high ratings and liking by leaders and has a very low level of role conflict and ambiguity. Tsui and O'Reilly (1989) discovered that gender dissimilarity between leader and member may lead to unfavorable social exchange due to low level of liking of members by leaders and high degree of role conflict.

LMX and OCB

The social exchange theory complements the foundation of LMX as the theory emphasizes on the purpose that leaders and members attempt to develop and maintain the exchange relationship (Graen & Scandura, 1987; Graen & Uhl-Bien, 1995; Sparrowe & Liden, 1997). Graen and Scandura (1987) concluded that leaders and members must provide something, which is perceived to be valuable by each party, and that the exchange must be balanced. In addition, employees not only require tangible materials but would also need social support in terms of psychological and emotional support. Further studies also supported that the exchange between leaders and members covers a range of specific resources such as information to emotional support. High quality of LMX comes from the perception of the value of material being exchange between leaders and members (Graen & Uhl-Bien, 1995).

Prior studies have revealed that LMX is influenced by the four main factors, which in turn become the determinant of the quality of the exchange relationship between leaders and members. As a result, the four dimensions may affect the quality of LMX in a work unit and thus influence the level of OCB exhibited by the employees. If the employees perceived the quality of LMX as high, this may encourage them to perform citizenship behaviors for the work unit and organizations. Scandura and Graen (1984) revealed that the cycle of citizenship behavior for reciprocal accomplishment of goals helps further strengthened the quality of the LMX. This is supported by other researchers, where they suggested that in-group members or a work unit that has a high quality of LMX may receive various types of rewards that are formal and informal (Settoon, Bennett, & Liden, 1996). Members would performed extra-roles by providing citizenship behavior to the supervisors who in exchange provide more mutual support and greater opportunities to the members.

Correspondingly, according to Deluga (1998), as a subordinate who perform OCB will not be formally rewarded, he or she may be informally rewarded in term of supplementary resources and support from the leader. Consequently, the subordinate will be motivated to continue to maintain the favorable relationship. Despite that, Aquino and Bommer (2003) noted that the person who received some benefits from others may indirectly have the tendency to return or feel obligated to return the favor and this interaction is known as

positive reciprocity. This kind of interaction can also be applied in the context of relationship between LMX and OCB. This is because when the leader trusted a particular subordinate and provide certain advantages to him or her in term of greater authority, more support and so forth, consequently the subordinate may feel to payback the favor to the leader. This can be done by performing behaviors that are beyond the formal employment contract, which is known as citizenship behaviors.

Taken together, LMX has significant influence on the level of OCB among employees as a high quality of LMX may motivate employees to exhibit extra-role behaviors without any formal rewards from the organizations.

RESEARCH METHODOLOGY

The respondents of this study are the executives employed in manufacturing companies located in Sarawak, Malaysia. A total of 10 manufacturing companies have been identified for this study. The questionnaires have been classified into two components where the first component is to determine the social exchange relationship between superiors and subordinates in a work unit. Meanwhile the other component of the questionnaires is to identify the level of OCB performed by subordinates in a work unit.

The relationship between superiors and subordinates were measured based on the questionnaires LMX-MDM developed by Liden and Maslyn (1998). This questionnaire has twelve items, which can be categorized into four dimensions so as to provide a multidimensional approach. From the perspective of OCB, there will be 20 questions used to determine the level of citizenship behaviors among subordinates based on five main dimensions. Likert-like scale will be used to measure both LMX and OCB elements, which ranks from 1 (Strongly Disagree) to 7 (Strongly Agree).

FINDINGS

Table 1 shows the demographic profile of the respondents.

Table 1: Demographic Characteristic of Respondents

Demographics		Frequency	Percentage
Subordinates' Gender	Male	63	61
	Female	40	39
Superiors' Gender	Male	69	67
	Female	34	33
Period of Working with Superiors	Less than 1 year	6	5.8
	1 - 2 years	48	46.6
	3 - 4 years	35	34
	More than 5 years	14	13.6
Races	Chinese	58	57
	Malay	20	19
	Others	25	24
Age (years)	16-20	4	3.9
	21-25	28	27.2
	26-30	39	37.8
	31-40	29	28.2
	41-50	3	2.9
Education Background	High school	32	31
	Diploma	39	37.9
	Degree	28	27.2
	Others	4	3.9
Working Experience	Less than 1 year	3	2.9
	1 - 5 years	62	60.2
	6 - 10 years	27	26.2
	More than 10 years	11	10.7
Monthly Gross Salary	Less than RM1,500	35	34
	RM1,500 - RM3,000	56	54.3
	RM3,001 - RM4,500	11	10.7
	RM4,501 - RM6,000	1	1
Nationality	Malaysian	94	91.3
	Non-Malaysian	9	8.7
Company Status	Locally Owned Company	81	78
	US Based Company	16	16
	Others	6	6

Table 2 presents the result of correlations and regression analysis. As can be seen from the table, LMX can explain 24% of the behavior of OCB. This indicates that there is a significant relationship between LMX and OCB with the Pearson Correlation at 0.494 and significance value at 0.000. Therefore, the level of exchange relationship between leader and member has a positive relationship on the level of organizational citizenship behaviors exhibited by the member in a work unit.

Table 2: Analysis Results

	OCB
LMX	0.49**
R^2	0.244
Adjusted R^2	0.236
F value	32.525**

** $p < 0.01$.

A total of five-2-step hierarchical multiple regression analysis was carried out to test the hypotheses that comprised the direct and interacting effects of LMX, gender on OCB. Table 3 tabulated the data obtained from these analyses. The following sections discussed the results.

Table 3: Hierarchical Regression Results Using Gender as a Moderator in the Relationship Between LMX and OCB

Independent Variable	altruism		courtesy		conscientious-ness		civic virtue		Sportsman-ship	
	R^2	Beta	R^2	Beta	R^2	Beta	R^2	Beta	R^2	Beta

Respect*Gender (Leader)		.80		.45		1.13		-.61		-.93

Note: *$p < 0.05$, **$p < 0.01$, $R^2 = R^2$ change for each step; Beta=Standardized beta coefficients.

Altruism

Altruism is one of the five dimensions in OCB. Step 1 was found to be significant (p>.01). Hence the direct effects of the predictors significantly explained 31% of the variability in altruism. Only one dimension in LMX-contribution was found to be significantly predictive of the altruism. The resultant incremental variance of 2% in entering step 2 was not significant. This indicated that the interaction effects of LMX and gender of the supervisors did not predict altruism element in OCB.

Courtesy

In the analysis of courtesy, step 1 was found to be significant (p<.01). Same as in altruism, contribution was found to be the significant contributor. Step 2 was found to be insignificant, therefore, collectively, the predictors did not interactively predicted the used of courtesy in OCB.

Conscientiousness

In analyzing conscientiousness, the main effects of the predictors are significant at .01 level (p<.01), explaining a total of 17% of the variability in the use of conscientiousness. It was found that contribution was the sole significant contributor in predicting the behavior of conscientiousness. Step 2 was not insignificant, indicated that collectively the moderating effect of gender on the relationship between interaction of the predictors and conscientiousness was not existed.

Civic Virtue

The analysis on civic virtue revealed that the main effects of the predictors on the criterion behavior were significant (p<.01). Specifically, contribution and gender of the supervisor were the significant contributors to civic virtue.

Sportsmanship

Step 1 was found to be significantly predictive of sportsmanship dimension in OCB (p<.01), explaining 15% of the variability. Two dimensions in LMX--loyalty and contribution, and gender were found to be significantly predictive of sportsmanship.

DISCUSSION AND CONCLUSION

LMX and OCB are two essential components related to establishing favorable relationship between superiors and subordinates and therefore motivate subordinates to perform extra-role behaviors. A number of researchers have revealed that there is significant relationship develop between LMX and OCB in a work unit. They also discovered that high quality of LMX would lead to positive behaviors or OCB being exhibited by subordinates. In this particular study, the outcomes of the analysis indicate that LMX has significant relationship with OCB in a work unit based on the data sample covering manufacturing companies in Sarawak.

Furthermore, the correlations result also indicated that the relationship between LMX and OCB is a positive relationship, which is congruent with the findings of Deluga (1994) as well as Settoon, Bennett, and Liden (1996). The significant relationship between LMX and OCB in this study is due to the high quality of social exchange developed between superiors and subordinates that have motivated the subordinates to perform citizenship behaviors in their respective workplace.

The study has proven where the strong positive correlation values for LMX determinants such as professional respect, affect, contribution, and loyalty, indicated that a high quality of social exchange is established between superiors and subordinates. This denotes that high quality of LMX between superiors and subordinates would induce the subordinates to attain a high level of OCB and vice versa. Therefore, this finding was also supported by other researches such as Hui, Law, and Chen (1999), where subordinates with a high degree of LMX or otherwise known as the in-group will perform higher degree of OCB. The main reason could be due to the fact that the interaction presented between superiors and subordinates is a reciprocal relationship and thus relies very much on the degree of exchange in term of access to information, support, time, and greater authority (Scandura & Graen,1984; Deluga, 1998).

Consequently, the favorable exchange relationship will bring about the citizenship behaviors from the subordinates. The act of performing extra-roles behaviors by subordinates is influenced by the fact that when subordinates receive or accept favors from their superiors, like for example, greater autonomy or minimum supervision, this will cause the subordinates to feel oblige to restore the good deed of their superiors by performing OCB. This is further supported by Aquino and Bommer (2003), where this relationship is known as positive reciprocity.

Based on these results, it may be concluded that the predictors were directly predictive of OCB particularly contribution dimension of LMX. The moderating effects of gender on the interaction terms of other predictors were not significant for OCB, indicated that gender did not affect the studied relationships as a moderator.

Gender similarity between superiors and subordinates did not affect the relationship between LMX and OCB. This is mainly because subordinates who performed citizenship behaviors in the workplace did so because of the high quality of social exchange, which existed between superiors and subordinates. This finding was supported by Duchon, Green, and Taber (1986) where gender similarity between superiors and subordinates would lead to high quality social exchange being established between superiors and subordinates. Correspondingly, this is further supported by Tsui and O'Reilly (1989), where gender similarity between superiors and subordinates would enhance the level of interpersonal liking, reduce role of conflict and ambiguity between superiors and subordinates, thus contributing to high quality of LMX.

On the other hand, gender dissimilarity between superiors and subordinates would also influence the subordinates to perform citizenship behaviors. The possible explanation for this phenomenon is due to the perception among male subordinates towards their female superiors (Terborg, 1977). Male subordinates may perceived their female superiors as inexperienced and have a lower level of authority as compared to male superiors. As a result, female superiors were unable to manage and influence their male subordinates effectively and subsequently would discourage male subordinates from performing extra-role activities in a work unit. Furthermore, the findings based on Stoeberl, Han, and Bae (1998) may as well provide further explanation on the gender dissimilarity issue, where female superiors were shown to be in a position when managing feminine group instead of the masculine group.

The other observation was that female superiors were unable to motivate male subordinates to perform citizenship behaviors although the level of LMX is high. Male superiors might have the tendency to delegate challenging tasks to male subordinates instead of female subordinates and this is probably due to their low level of confidence on the female subordinates' capability. As a result, female subordinates in this study would view the social exchange relationship with their male superiors as inequitable or discriminatory.

The perceived unbalanced treatment by male superiors towards their female subordinates as compared to male subordinates would thus discourage female subordinates from performing citizenship behaviors in the workplace. In addition to that, the fact that male superiors had less influence on the feminine group as based on Stoeberl, Han, and Bae (1998), could also be the possible reason behind the inability of male superiors in motivating female subordinates to performed extra-role activities that are not specified in the job description.

ABSTRACT

Although it is recognized that the knowledge economy has arrived, and that knowledge is a key business asset, organizations are still in the early stage of understanding the implications of knowledge management. Knowledge management is promoted as an important and necessary tool for organizations in obtaining competitive advantage. This study draws attention to the process of knowledge management in law firms in Johor Bahru. The process includes knowledge identification, knowledge acquisition, knowledge application, knowledge sharing, knowledge creation and knowledge preservation. A mail survey was conducted on 205 legal firms in Johor Bahru. Of this, only 53(25.9%) duly completed and returned the survey questionnaires. It was found that generally, law firms in Johor Bahru do implement knowledge management. Results also indicated that knowledge application was the most widely used amongst the respondents whilst knowledge creation was the lowest. The relationship between each process of knowledge management and firm's reputation was also identified in this study. It also points out that knowledge management has positive correlations with firm's reputation. Recommendations to enhance knowledge management in the legal professions are also presented.

INTRODUCTION

The Eighth Malaysia Plan, was launched in 2001 as the first phase of the Third Outline Perspective Plan (2001-2010), with the intention to translates into action the National Vision Policy that aims at enhancing competitiveness and strengthening economic resilience. In line with this plan, policies were drafted in mind to achieve sustainable growth with macroeconomic stability. These policies include encouraging further domestic and foreign investment, improving productivity and innovation, enhancing technological development, developing quality human resource as well as accelerating the transition to a knowledge-based economy. That the Malaysia's government commitment to accelerate the transformation to a knowledge-based economy was seen with the launching of the Knowledge-Based Economy Master Plan (KEMP) in 2002. The KEMP contains 136 recommendations encompassing human resource development, infostructure, incentives, science and technology development, reorientation of the private and public sectors as well as addressing the digital divide. The Government also monitored the progress towards a knowledge based economy on the basis of the Knowledge-Based Economy Development Index5 (KDI). Currently, Malaysia remained at 17th position and still continued to remain ahead of the developing regional economies in this aspect.

The government efforts did not go unnoticed by the Malaysian researchers. Study by Narayanan, Richardson and A. Latif (2003) on engineering companies in Kuala Lumpur indicated that 65% of the respondents agreed that costly mistakes could be avoided had employees possessed sufficient knowledge or expertise. Thus, enterprises which leverage its intellectual resources can alter its competitiveness. Leading firms therefore are finding that, to remain competitive, they must managed their organization's knowledge and expertise as uses it as a tool to increase firm's competitive value.

PROBLEM STATEMENT

Knowledge embedded in the organization's business processes and employees' skills provide firms with unique capabilities to deliver customers with a product or service. The need to manage knowledge actively becomes more obvious when what you sell is knowledge. Consulting firms like the legal fraternity represent an industry, which seems well suited for knowledge management investigation (Lamb, 1999). They are knowledge intensive, and the use of advanced technology may transform these organizations in the future (Gottschallk, 1999). Furthermore, consulting firms had always considered knowledge to be a core capability for achieving competitive advantage (Chard, 1997; Pasternack & Viscio, 1998). Hence, knowledge management has become the logical path for these firms to take. This is made even more critical if the organization's knowledge is held under the custody of a few, which generally sums up the environment of the legal profession. Pasternack and

Viscio (1998, p.96), proposed that "where much of the key knowledge is held by individuals, unless there is some structure to retain it within the organizational memory, when a person leaves the organization a mass of knowledge goes right out the door with that person".

The question now is whether legal firms in Malaysia realize the importance and the role of knowledge management, KM as a competitive tool to increase a firm's competitive advantage. Do they realize the effects of KM on their firm's performance? This study is done to identify the relationship between KM and competitiveness in the legal profession.

OBJECTIVE OF THE STUDY

The purpose of this study is to determine whether legal firms in Johor Bahru Bahru implement knowledge management and if they do to what extent. The researchers also wish to identify the   relationship between knowledge management and firms' financial performance. The legal firms were chosen in this study because of their impacts on the social web of Johor and the proximity of Johor Bahru to Singapore where competition from across the border is very real especially in relation to international activities.

LITERATURE REVIEW

Clarke and Rollo (2001) define data as a set of discrete objective facts, which is presented without judgement or context. Information is the output of data that is categorized, analyzed, summarized and placed in context so as to become intelligible to the recipient. In other words, data becomes information when it is manipulated, represented and interpreted to reduce uncertainty, give surprises or insights and allow or improve decision-making (Earl, 1983). When information is used to make comparisons, assess consequences, establish connections and engage in dialogues, knowledge is then created. Hertog and Huizenga (1997) defined knowledge as a collection of information and rules with which a certain function can be fulfilled. Weggeman (1997) sees knowledge as a personal capacity and it is the product of the information, the experience, the skills and the attitude, which someone has acquired at a certain point in time.

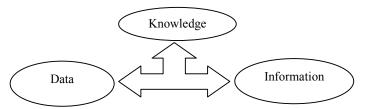
According to Bhatt (2001), data is considered as raw facts while information is an organized set of data. When information becomes meaningful it is perceived as knowledge. The relationship between data, information and knowledge is recursive. Raw data is selected according to its relevance to the user. It is then processed so that the data becomes information. The application of information contributes to the creation of knowledge. Thus, knowledge refers to the capability to interpret data and information through a process of giving meaning to the data and information as illustrated below.


Figure 1 : The recursive relations between data, information and knowledge
Source : Ganesh D. Bhatt, 2001, p.69

"Knowledge is usually divided into explicit and tacit knowledge" (Preiss, 1999, p.37). Tacit knowledge is the unarticulated knowledge. It is in a person's head and difficult to describe and transfer. This type of knowledge includes lessons learned, know-how, judgment, rules of thumb, and intuition (O'Dell & Grayson, 1998). Tacit knowledge is also automatic, requires little time or thought and helps determine how organizations make decisions and influence the collective behavior of their members (Liebowitz & Beckman, 1998). According to Smith (2000), tacit knowledge at the workplace is practical, action-oriented knowledge that is acquired through personal experience, is seldom expressed openly and often resembles intuition. Although the effective utilization of tacit knowledge is essential for competitiveness, the problem with tacit knowledge is that it is difficult to capture. Tacit knowledge is embedded in company practices and also the people in an organization. Thus, it is highly personalized, context-sensitive and very difficult to measure and manage (Clarke & Rollo 2001).

Explicit knowledge refers to the knowledge that exists in a given collection of data and rules in a reasonable time (Bollinger & Smith, 2001). It can be expressed in words and numbers. It can be shared in the form of data, scientific formula, specifications and manuals (Civi, 2000). It can also migrate into the business community and

made accessible to most companies regardless of their active cooperation. Compared to tacit knowledge, explicit knowledge is clearly formulated, easily expressed without ambiguity, then codified and stored in a database where it can be accessed and used easily by the individuals in an organization. Once codified, explicit knowledge assets can be used to solve many similar types of problems or connect people with variable and reusable knowledge (Smith, 2001).

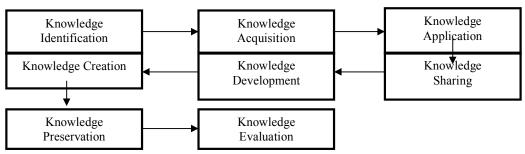
Knowledge management, KM according to Davenport *et al.* (1998), means exploiting and developing the knowledge assets available to the organization in achieving organizational objectives. It embodies the management of the two branches of knowledge namely explicit and tacit knowledge. The management of knowledge includes a few processes namely knowledge identification, sharing and creation. These processes require systems to create and maintain knowledge repositories, to cultivate and facilitate the sharing of knowledge and organizational learning. Bhatt (2001) defines KM as a process of creating, validating, presenting, distributing and applying knowledge. These five phases in KM allows an organization to learn, reflect and unlearn and relearn. However, knowledge is not static (Malhotra, 1998). Knowledge that is acquired needs to be evaluated over time to ensure its relevance. Hence, the element of knowledge preservation and knowledge evaluation need to be incorporated into KM. These elements are as shown:


Figure 2: The eight elements of KM process
Source : Frank Management Center, 2002

Competitive tool refers to the accessories, which gives a competitive edge in the bid to achieve a goal. The competitive tool is essential in creating the existence of a competitive advantage for a firm. Bharadwaj et al. (1993) highlighted the importance of organizational learning and expertise as a source of competitive advantage. The further definition noted by Winter (1987), who suggested that organizational learning will be a source of competitive advantage if the learning is "tacit" and if the underlying knowledge is complex. It is because this will result in making imitation difficult. Osbaldeston and Barham (1992) argued that management development can become a source of competitive advantage. By linking management training and development to business strategy, management can become a way to reshape organizational culture, and implement strategies. This argument is supported by Swiercz and Spencer (1992), who proposed that human resources, if managed correctly, provides a valuable source of competitive advantage. Building on this, in a fast-changing environment like the legal profession, the ability to exploit the power of knowledge development will definitely leverages an organization against its competitors

METHODOLOGY

The survey method was employed in this study. The instruments were divided into three sections consisting of respondent's demographic information, a list of 25 items related to the eight components of KM and perceptions on firm's reputation. The list of 25 items related to KM consists of a 5-point Likert scale. Respondents must rate their agreements on each statement on a scale ranging from 1 (strongly disagree) to 5 (strongly agree). Respondents consist of managing director or equivalent from the legal firms in Johor Bahru. 205 questionnaires were distributed out of which 53 questionnaires were returned and analysed. Principle component factor analysis was performed on the KM instruments to determine its construct validity. Reliability analysis was also conducted to ensure the internal reliability of the said instrument. Correlations were conducted to determine the relationship between KM and the perceptions on firm's reputation.

FINDINGS

The survey instrument was tested for reliability and it yielded a Cronbach's Alpha value of 0.8664. This indicated that the instruments have the necessary reliability for statistical analysis. Cronbach's Alpha was used as it can be considered an adequate index of the inter-item reliability of independent and dependent variables (Sekaran, 1992).

Factor analysis was performed to determine whether the specific items in section two of the instruments that made up each theoretical construct were clustered together. In other words it seeks to confirm the dimensions of the concept that have been operationally defined and indicate the appropriateness of each items for each dimensions.

Based on Table 1, the relatively high value of 0.844 for the Kaiser-Meyer-Olkin Measure of sampling adequacy indicates that the proportion of variance in the variables are caused by underlying factors hence allowing for the application of factor analysis. This is also supported by the Bartlett's test of Spherecity value of 0.00 which is less than 0.05 proving that the analysis is appropriate.

Table 1: KMO and Bartlett's Test

Kaiser-Meyer-Olkin Measure of Sampling Adequacy		0.844
Bartlett's Test of Spherecity	Approx. Chi Square	593.324
	df	231
	Sig.	0.000

The results of the principal component factor analysis, based on VARIMAX rotation using an Eigen value of one or greater as the criterion test, suggests a six-factor solution to KM instrument. However, two of the factors were dropped for further analysis since it does not have the reliability values of 0.7 or greater (Nunnally, 1978). Further examination of the items loading on each factor resulted in the following label being applied to the various factors:

Table 2

Factor 1	Knowledge identification
Factor 2	Knowledge acquisition
Factor 3	Knowledge sharing
Factor 4	Knowledge creation

A summary of the rotated factor analysis variables found in this study is presented in Table 3. Reliability analysis of these three factors shows satisfactory alpha values (more than 0.7).

Table 3

Item	Factor			
	1	**2**	**3**	**4**
The firm dedicates resources to detecting and obtaining external knowledge and communicating it within the organization.	.787			
The firm has some form of database to capture information and experience gained from accomplished projects.	.661			
The firm regularly identifies the type of business information relevant for the firm's usage	.722			
The firm encourages the use of knowledge database to identify and obtain related information in order to improve work process amongst members of the organization.	.632			
The firm acquires and uses knowledge obtained from external sources such as industrial associations, competitors, clients, suppliers, including universities and government organizations.		.795		
The firm improves customer satisfaction by implementing acquired knowledge in terms of public relations.		.826		
The firm regularly updates information which consists of good work practices, lessons learned, expert directory etc.		.649		
The firm updates and evaluates it databases frequently to ensure that they have the latest information.		.615		
The firm facilitates collaborative work by different project teams.			.844	
The firm regularly assigns project team work to improve the current work process.			.696	
The firm encourages mentor-mentee relationships among workers.			.757	
The firm sends employees to seminars, conferences etc. on regular basis to enable them to learn new knowledge and improvise their knowledge to suit the firm's need.				.844
The firm emphasizes on Research and Development (R&D) in an effort to create new knowledge.				.794
Cronbach's alpha	.7893	.7788	.7089	.7956

* only loading having absolute value greater than 0.600 are shown

Results of factor analysis show that there are four reliable dimensions of KM construct. Factor 1 (knowledge identification) refers to the identification of knowledge and know how related to a particular problem. Factor 2 (knowledge acquisition) consists of four items which focuses on the process of acquiring needed knowledge and applying it onto a particular set of problems. It also refers to updating firm's database on a regular basis. Factor 3 (knowledge sharing) offers insight to the sharing of tacit as well as explicit knowledge amongst members of the organization. The fourth factor (knowledge creation) suggests the creation of new knowledge by members of the organization through the amalgamation of member's knowledge and the latest legal information gained via research or experts gathering. Table 4 shows the mean score and standard deviation of each of the four KM construct. Results indicated that respondents tend to be 'moderately agree' on the items related to the KM construct.

Table 4

	N	Minimum	Maximum	Mean	Std. Deviation
Knowledge identification	53	1.00	5.00	3.8774	.7266
Knowledge acquisition	53	1.00	5.00	3.5943	.7583
Knowledge sharing	53	1.00	5.00	3.3208	.9204
Knowledge creation	53	1.00	5.00	3.2736	.9434
Valid N (listwise)	53				

The correlation between the independent variables and dependent variable are shown in Table 5. Variables such as 'knowledge identification', 'knowledge acquisition' and 'knowledge sharing' and firm's reputation are significantly correlated at $p = 0.05$. 'Knowledge creation' is not supported due to insignificant correlation ($p > 0.05$).

Table 5: Correlations

Spearman's rho			Firm's reputation
	Knowledge identification	Correlation Coefficient	.415**
		Sig. (2-tailed)	.002
		N	53
	Knowledge acquisition	Correlation Coefficient	.445**
		Sig. (2-tailed)	.001
		N	53
	Knowledge sharing	Correlation Coefficient	.292*
		Sig. (2-tailed)	.036
		N	53
	Knowledge creation	Correlation Coefficient	.127
		Sig. (2-tailed)	.369
		N	53

** Correlation is significant at the .01 level (2-tailed).
* Correlation is significant at the .05 level (2-tailed).

DISCUSSION AND CONCLUSIONS

Overall, the findings of the study seem to indicate that legal firms in Johor Bahru do implement KM albeit on the moderate scale and it is largely confined on the following area:

1. the identification and detection knowledge needed to the industry.

2. the acquisition and application of acquired knowledge in order to improved client satisfaction.

3. the sharing of acquired knowledge amongst members of the organization.

4. the creation of new knowledge through innovation.

Identification and acquisition of knowledge seems to be the main features of the KM process in the legal industries while the creation of knowledge the least featured. In other words, legal firms put more efforts in determining the type of business information that is relevant for the firm's use and have proper procedure in identifying knowledge according to its importance to the organization. However, firms seldom promote activities related to knowledge creation such as reconfiguring and recombining existing pieces of knowledge along with imitation, substitution and replication strategy.

Knowledge is of less value to the organization if it resides in individuals. Hence, many international firms have made a substantial effort trying to create, transfer and share knowledge within organizations to enhance their profit generation capability (Laurie, 2002). Knowledge sharing is a set of behaviors that involve the exchange of information or assistance to others. It differs from information sharing because it contains an element of reciprocity and is usually requested (Connelly & Kelloway, 2003). Studies have found that knowledge sharing is encouraged by increased social interaction. This could be because people are more likely to share knowledge with their friends and social interaction increases the likelihood of an employee making friends with colleagues (Connelly & Kelloway, 2003). Thus, it is important for the legal firms in Johor Bahru to encourage social interaction amongst its' employees as knowledge sharing fares rather poorly.

The creation of new knowledge is the most popular topic in today's management literature (Binney, 2001). The focus of the business and knowledge creation is on providing an environment in which knowledge workers of various disciplines can come together to create new knowledge. This is because existing know-how and best practices which assumes that all organizations are roughly alike may not be relevant to future aspirations. Employees access and use corporate know-how without reviewing and updating it, or validating it. They do little to replenish the supply of organizational knowledge by supporting processes for creating new knowledge (Coulson-Thomas, 2004). Since legal firms score rather miserably in this area, they should starts identifying individuals who are able to add to the pool of collective understanding and best practice. These creators of new knowledge may not necessarily be the silver-tongued or the best presenters. Sometimes they find themselves the victims of de-layering, headcount reductions and ageism.

Knowledge identification, knowledge acquisition and knowledge sharing were found to have positive but relatively weak correlations with firm's reputation. The weak correlations are expected due to the nature of KM itself and the multifactor influence of organization's reputation. According to Dunford (2000), despite the pervasiveness of the view that KM is a core component of competitiveness, its specific contribution to revenue or firm's image is very difficult to determine. Hence, though it is generally agreed that KM is important to the legal business, some of the firms have not put in enough effort to develop this area.

The emergence of the hyper-competitive global economy and the coming of knowledge age have drove organizations to manage their resources more effectively. Management is increasingly aware that knowledge resources are essential to the development of their organizations. Hence, managers must understand their positions in relation to their competitors as well as their customers' attitudes and perceptions. Knowledge management is valuable because it can be useful for decision making as well as for strategic formulation making it a competitive tool.

ABSTRACT

Recent research on Information Systems (IS) Success has adapted the Contingency Theory in assessing the "success" of information system. This study focuses on further theoretical and empirical development of this important belief in IS Success. Specifically, unlike prior research which has re-specified the IS model, this research will instead study the impact of some independent variables on the model itself. Some elements of Organisational Structure and Organisational Culture have been proposed to have an impact on the IS Success model and has been theoretically justified. Based on the conceptual definition of the selected elements of the Organisational Structure, Organisational Culture and IS Success, this study develops operational measures of them. The model is tested on 31 users of Citibank Information System. Partial Least Square (PLS) technique was used to estimate the parameters of the proposed model. The study findings indicate that neither one factor under organisation structure nor one factor under culture has significant impacts on Information Systems success. Implications of the results are highlighted.

INTRODUCTION

Empirical research into the successful development of information systems has been filled with difficulties (Garrity and Sanders, 1998). The role of Information Technology continues to expand in scope and complexity and as such IS researchers and professionals are facing problems in defining the theories and criteria for judging information system success. Despite all the previous work related to system success, inconclusive findings in empirical studies of information systems development might be due to the inadequate dependent measures of IS success.

Previous studies have formulated six dependent variables (that is: System Quality, Information Quality, Use, User Satisfaction, Individual Impact and Organisational Impact) that could contribute to the success of an organisation's Information Systems (DeLone and McLean, 1992). The availability of other variables that could contribute to the overall Information Systems Success has also been considered. Based upon these foundations, this study has augmented Information Systems Success Model with two new independent variables. These variables, Organisational Structure and Organisational Culture, were quantified and tested against the dependent variables of Information Systems Success.

Recognising the limited perspective of the original Information Systems Success Model, it is therefore, the core theme of this research to contribute to the literature, by "confirming" to a certain extent the conceptual development and refinement of the dependent measures. The knowledge acquired from this research would also seek to confirm the importance of Organisational Structure and Organisational Culture as two of the independent variables in the Information System Success Model.

The analysis uses a structural equation modelling approach with partial least squares (PLS). PLS, a second-generation multivariate analysis technique, embraces abstract and empirical variables simultaneously, and recognises the interplay of these two dimensions of theory development (Igbaria et al, 1995).

The reminder of this paper is organised as follows. The next section provides a brief but critical review of the literature. The subsequent section presents the research model and hypotheses. Details of the empirical study

and the statistical analyses are then presented. The final section summarises the application and highlight important findings.

CONCEPTUAL BACKGROUND

Information Systems Success

The Information Systems Success Model proposed by DeLone and McLean (1992) is based on the work of Shannon and Weaver (1984) and Mason (1984), and other published papers which address the issues of IS success (Figure 1). Though there is not one success measure, DeLone et al confirmed that these measures fall into six major categories. These categories are interrelated and interdependent, forming an IS Success model. SYSTEM QUALITY and INFORMATION QUALITY singularly and jointly affect both USE and USER SATISFACTION. Additionally, the amount of USE can affect the degree of USER SATISFACTION – positively or negatively – as well as the reverse being true. USE and USER SATISFACTION are direct antecedents of INDIVIDUAL IMPACT; and lastly, this INDIVIDUAL IMPACT on performance should eventually have some ORGANISATIONAL IMPACT (DeLone and McLean, 1992, pp.83-87).

This model has since been used as a basis for empirical research, and has been refined and extended by a number of researchers (such as Fiedler et al, 1996; Seddon et al, 1994; Pitt et al, 1995; Ballantine et al, 1998; Garrity et al, 1998; Saunder et al, 1992; Myers et al, 1998).

Motivated by DeLone et al's call for further development and validation of their model, Seddon and Kiew (1994) critically examined the meaning of the four of the taxonomy in the IS Success Model. They suggested that user involvement is a fundamental factor that should be present. Their empirical results provided substantial support for DeLone and McLean's model. Pitt, Watson and Kavan (1995) have produced an augmented model which includes the appropriateness of SERVQUAL to assess IS service quality. Recognising the expanding function of the IS department, their major contribution to the study demonstrates that SERVQUAL, an extensively applied marketing instrument for measuring service quality, is applicable in the IS arena.

Over the years, the Contingency Theory of Information Systems continues to evolve. Adapting from Saunders and Jones (1992), the contingency theory for IS assessment would use selected measures for each assessment dimension and selected organisational and external environmental variables. The most recent research by Myers et al (1998) examined the need for the IS assessment and suggested a comprehensive IS assessment framework linked to organisational performance using existing IS assessment theory as a base and incorporating measurement concepts from other disciplines. The existing models of IS success are updated to include the emerging IS success dimensions of service quality and work group impact and provide a comprehensive method for organising the various measures of IS success (Figure 2). This theoretically-based, comprehensive set of IS assessment measures and a contingency theory for selecting appropriate measures will hopefully provide IS managers with the guidance necessary to develop their own IS assessment systems. These assessment systems have the potential to furnish the feedback required to enhance the quality and productivity of the IS function and hence the organisation.

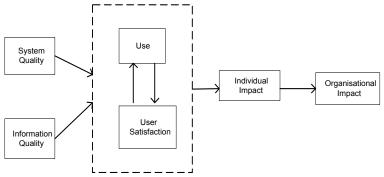
The notion of culture and structure has been used as possible dimension to effective IS management. Meyer (1996) talks about culture and structure (in addition to internal economy, methods and metrics) as two of the five dimensions of an organisation design which an effective management should call for in order to be competitive in this changing economic condition. Ishman (1998) proposes a questionnaire to be added to the inventory of well-developed management information system instruments. Tested on cross-cultural environments, this research confirmed that the factors that have influenced successful outcomes at the individual level in a domestic environment are applicable in a global environment (Ishman, 1998).


Figure 1: The Original IS Success Model (DeLone and McLean, 1992)

To conclude, the above brief literature review has supported the idea that Information Systems Success would be affected by other variables especially presented in the IS Assessment Selection Model by Myers et al (1998). However, sensing the gap that no research had actually been done to test the impact of some of these variables on IS success, this study has selected two of the variables from the Contingency Theory Variables, that is, Organisational Structure and Organisation Culture as two of the independent variables in the Information System Success Model. It is also the main aim of this study to find new directions to investigate the importance of other independent measures of Information Systems Success, for future research.

Organisational Structure

The evolution of structural designs throughout the century has seen organisations grew from the original simple structure, to becoming bureaucracies, and the rise of modern large corporations. Organisation Structure is the organisation's system of task, reporting, and authority relationships within which the organisation does its work – ie. how jobs are formally divided, grouped, and coordinated. Due to the differences in strategies and environmental circumstances, Organisation Structure would undoubtedly differ from one another.

Figure 2: A Comprehensive IS Assessment and Contingency Theory (Selecting the Measures) – Myers et al, 1998

Organisational Structure can in turn be "measured" by the structural variables like (Robbins, 1998): Work Specialisation- the degree to which tasks in the organisation are subdivided into separate jobs; Departmentalisation - the manner by which divided tasks are combined and allocated to work groups; Chain of Command - the unbroken line of authority that extends from the top of the organisation to the lowest echelon and clarifies who reports to whom; Span of Control - the number of subordinates a manager can efficiently and effectively direct; Formalisation – the degree to which jobs within the organisation are standardised; Centralisation and Decentralisation - Centralisation is the degree to which decision-making is concentrated at a single point in the organisation and Decentralisation is the decision discretion that is being pushed down to lower-level employees.

There has also been vast research done in relation to Organisation Structure and Information Systems, and hence the overall business strategy, such as Pankratz (1991) who studied impact of information technology (IT) on business management in the 1990s. Carlson et al (1999) did a study on Organisational Impacts of New Communication Technology. His research studied whether cellular phones have an effect on decision-making in the organisation, and tested which of the variables described by Huber (1990) might be influential in any changes in decision making (these four independent variables are: centralisation-decentralisation, levels of management, standardisation, and formalisation). Hofstede et al (1990) did a comprehensive study in Denmark and the Netherlands and touched on the relation between culture and other organisational characteristics. They measured structure in terms of span of control, percentage of supervisory personnel, centralisation score, specialisation score and formalisation score. Hult et al (1997) measured part of structure in terms of Centralisation and Formalisation.

To date most of the literature only touched on the impact of Information Systems (or Technology) on the design of an Organisation Structure but rarely the other way. Sensing this gap, it is hoped that this research could contribute to the literature that there is also an impact of Organisation Structure on Information Systems development and success.

Organisational Culture

An organisation's current customs, traditions, and the general way of doing things are largely due to what it has done before and the degree of success it has had with those endeavours (Robbins, 1998). This could be traced back to the ultimate source of an organisation's culture: its founders. The founders traditionally have a major impact on the original culture of an organisation. They have a vision of what the organisation should be. Once a culture is in place, practices within the organisation act to maintain it by giving employees a set of similar experiences. Many of the human resource practices such as the selection process, performance evaluation criteria, reward practices, training and career development activities, and promotion procedures ensure that those hired fit in with the culture, reward those who support it, and penalise those who challenge it.

Organisational Culture therefore refers to *a system of shared meaning or common perception held by the members that distinguishes the organisation from other organisations* (Robbins, 1998). This system of shared meaning is actually a set of seven key characteristics that the organisation values: Innovation and Risk Taking – the degree to which employees are encouraged to be innovative and take risks; Attention to Detail – the degree to which employees are expected to exhibit precision, analysis, and attention to detail; Outcome Orientation – the degree to which management focuses on results or outcomes rather than on the techniques and processes used to achieve these outcomes; People Orientation – the degree to which management decisions take into consideration the effect of outcomes on people within the organisation; Team Orientation – the degree to which work activities are organised around teams rather than individuals; Aggressiveness – the degree to which people are aggressive and competitive rather than easygoing; Stability – the degree to which organisational activities emphasise maintaining the status quo in contrast to growth. Each of these characteristics exists on a continuum from low to high. Appraising the organisation on these seven characteristics would give a composite picture of the organisation's culture (Robbins, 1998).

There has also been vast research done in relation to the importance of Organisation Culture and Information Systems, and hence the overall business strategy. Robson (1994) noted the complex cultural web of an organisation that needs to be analysed. This is because the organisational culture is the element that ensures that, faced with the same set of circumstances in the environment and internal resource constraints, organisations respond in different ways. The culture of the organisation defines their measures of success, or recipe. This recipe can have a dampening effect upon the influence of environmental factors and hence upon strategy.

Malone (1994) noted that it is impossible to underestimate the impact of human emotions on the success or failure of technology in the workplace. Hasan et al (1999) conducted a study on the relationship between culture and the adoption of IT in two different developing regions. One of the three major issues they found was that: the success of information systems in organisations is dependent on the activities of people who carry with them a pattern of thinking, feeling and acting which is learnt through their culture. They then concluded that in order to make most effective use of IT, people should choose a product that supports the work practises determined by their own culture.

To date most of the literature only touched on the impact of Information Systems (or Technology) on Organisation Culture but rarely the other way. Sensing this gap, it is hoped that this research could contribute to the literature that there is also an impact of Organisation Culture on Information Systems Success.

RESEARCH MODEL AND HYPOTHESES

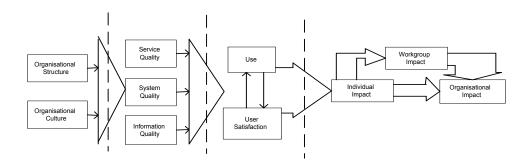
Figure 3 presents the proposed impact of organisation structure and culture on Information Systems Success. The relationship between Information Quality, System Quality, Service Quality, Use, User Satisfaction, Individual Impact, Work Group Impact and Organisational Impact derive directly from the revised model of IS Success by Myers et al (1998). In their paper Myers et al (1998) examined the need for IS assessment and suggested a comprehensive IS assessment framework linked to organisational performance using the existing IS assessment theory as a base and incorporating measurement concepts from other discipline. They presented a theoretically-based, comprehensive set of IS assessment measures and a contingency theory for selecting appropriate measures that would provide IS managers with guidance necessary to develop their own IS assessment systems. They believed that these assessment systems would have the potential to furnish the feedback required to enhance the quality and productivity of the IS function and hence the organisation.


Figure 3: The Impact of Organisational Structure and Organisation Culture on Information Systems Success

Parallel with the work of Myers et al (1998), this research will "extend" the IS Success to include some elements of Organisation Structure and Organisation Culture as these elements are some of the "Organisational Environment" (Myers, 1998) which are believed to have impacts on IS Success.

The model proposed that organisational structure and organisational culture act as the independent variables (them being representative of the contextual and environmental characteristics of Shore (1998)). We retained the IS Success model as it is. Thus the independent variables theoretically impact the first three elements of the IS model that is, Service Quality, System Quality and Information Quality. It is noted that "Decentralisation", "Formalisation", and "Work Specialization" are used as proxy for organizational structure. On the other hand, "Innovation/Risk Taking", "People Orientation", and "Stability" are used as proxy for organizational culture.

The structural equation modelling (SEM) approach is used to test various hypotheses. Figure 4 shows the full blown IS success model in our study. This model is divided into two parts: the organisational structure and culture being one aspect of the measurement (Confirmatory Factor Analysis (CFA)) model and the other being the information system success thus forming a complete CFA Model.

Fourteen constructs, each with its unique composite variables, form the confirmatory "structural" model, with relationships specified in accordance with the proposed theory that Organisation Structure and Culture impact the Information Systems Success.

Based on the proposed model and extensive literature review, the following hypotheses are proposed:

Organisational Structure:
H1: Decentralisation has positive impact on Information Quality
H2: Decentralisation has positive impact on System Quality
H3: Decentralisation has positive impact on Service Quality
H4: High Formalisation has negative impact on Information Quality
H5: High Formalisation has negative impact on System Quality
H6: High Formalisation has negative impact on Service Quality
H7: Work Specialisation has positive impact on Information Quality
H8: Work Specialisation has positive impact on System Quality
H9: Work Specialisation has positive impact on Service Quality

Organisational Culture:

        H10: Innovation/Risk Taking has positive impact on System Quality
        H11: People Orientation has positive impact on Information Quality
        H12: People Orientation has positive impact on System Quality
        H13: People Orientation has positive impact on Service Quality
        H14: Stability has positive impact on Information Quality
        H15: Stability has positive impact on System Quality
        H16: Stability has positive impact on Service Quality

Other hypothesised links of Figure 4 are similar to the previous studies on IS Model (DeLone et al, 1992, Myers et al, 1998, Pitt et al, 1995, Seddon et al, 1994)

RESEARCH METHODOLOGY

Sample and Procedure

Data were collected using a questionnaire based survey. The survey was distributed to the staff of Citibank NA, Brunei. The bank was chosen as it acts as a representative of a financial institution in this research.

What Citibank NA Brunei practises now is the Bank-in-a-box application. This means that the Information Systems are integrated and the most commonly use systems are: COSMOS which is a Back-end system that handles book records on deposits and loans; CR Management System which is another Back-end system; CITIBANKING which is the Front-end system that faces customers; CATZ which is another Front-end system that deals with ATMs and directly handles customers; Middle Office System that helps with the workflow; SMART which is a report archiver and is online; WEB-based applications; E-mail; and special requirement for each department such as CORONA that consolidates accounts with other Citibank branches.

In Brunei Citibank NA has only two offices: one in Bandar Seri Begawan and the other at Kuala Belait, with a total number of 54 employees.The questionnaires were distributed through three managers of the bank. All respondents were guaranteed confidentiality of individual responses, and a response rate of 57.4% was obtained. Most of the surveys were obtained from staff between the age range of 25-34, with 61.3 percent of them being females. 35.5 percent have GCE O Levels or below qualification with 10-19 years of working experiences at the bank.

ANALYSES AND RESULTS

To test the research hypotheses, partial least squares (PLS) analysis was used. PLS is a second-generation multivariate analysis technique used to estimate the parameters of causal models (Igbaria, 1995). PLS embraces abstract and empirical variables simultaneously, and recognises the interplay of these two dimensions of theory development. These second generation techniques are superior to traditional regression and factor analysis because the items measuring a construct are assessed within the context of the theoretical model. The PLS technique is particularly applicable in research area where theory is not as well developed as that demanded by LISREL (Fornell et al, 1982). In addition to that, PLS does not depend on having multivariate normally distributed data, and most importantly PLS can be used with small samples. The computer program used for this analysis was PLSGraphv3.0 (Chin, 2001).

Although the parameters are estimated together, a PLS model is analysed and interpreted in two stages: (1) the assessment of the reliability and validity of the measurement model, and (2) the assessment of the structural model.

With PLS, a causal model such as Figure 4, would be recognised as having two components: the measurement model and the structural model. Relationships or paths among theoretical constructs are described fully in the model. Each construct in turn would have links with a set of items. The measurement model would therefore consist of the relationships between the observed variables (items) and the construct they measure. This model would also evaluate the extent to which the operationalisation of a construct actually measures what it is supposed to measure – ie. construct validity. Two important dimensions of construct validity are (1) convergent validity, and (2) discriminant validity.

Measurement Model

Testing the measurement model includes the estimation of the reliability coefficients of the measures, and also an examination of the convergent and discriminant validity of the research instrument. To determine the appropriate minimum loadings required for the inclusion of an item within a scale, this study used the guidelines recommended by Hair et al (1992) in Igbaria et al (1995), that is, loadings greater than 0.30 are considered significant; loadings greater than 0.40 are considered more important; and loadings 0.50 or greater are considered to be very significant. Nunnally's (1978) guideline for assessing reliability coefficient was used for evaluating composite reliability of each scale. And to assess the average variance extracted (AVE) for all constructs, the guideline of Fornell and Lacker's (1980) and Igbaria et al (1995) was used where AVE should be more than 0.5.

Reliability coefficients of the latent variables vary from 0.655 to 0.953, which satisfies Nunnally's guideline. It is noted that "Stability" includes three items instead of four. One item was eliminated after the first PLS run because its factor loading was lower than 0.4. Two items from "Use" have also been eliminated due to the low item loadings. The low values suggest that further research is required to refine the measurement of theses constructs and improve convergence (Rivard and Huff, 1988).

Correlations of constructs

In order to assess the discriminant validity of the measures, this study examined the correlations between the constructs. The measure is said to have adequate discriminat validity, if the items comprising an instrument that measures a construct correlate more highly with each other than with items measuring other constructs in the model. The assessment of discriminant validity of this study does not reveal any serious problems.

Loading and Cross-Loading of Measures

The primary criterion for discriminant validity is that each indicator must load more highly on its associated construct than on any other construct. The factor pattern matrix (from PLS software) was constructed which showed the loadings of each item on all constructs. To save space this table is not presented here. The results of cross-loadings are satisfactory and therefore discriminant validity is maintained.

Structural Model

The structural model is also tested by PLS. With its roots in path analysis, the structural model is analyzed using a regression-based technique that consists of the unobservable constructs and the theoretical relationships among them (paths). The hypotheses to be tested are also represented by the significance of this model. Both the structural and measurement models form a network of constructs and measures. The strength of the measures is indicated by the item weights and loadings whilst the strength and sign of the theoretical relationships is indicated by the estimated path coefficients. Figure 5 shows the path coefficients generated from PLS analysis.

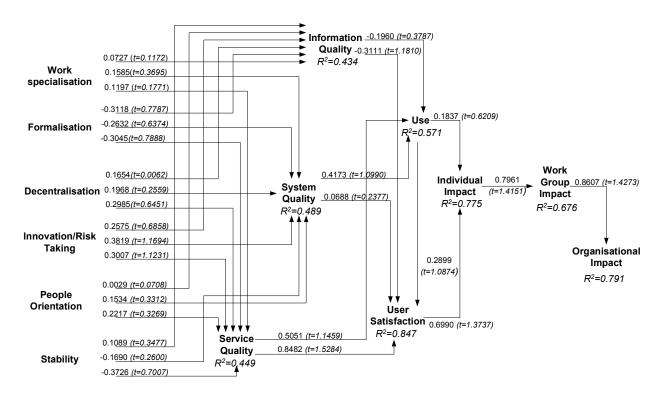
Jackknifing was used to calculate the statistical significance levels for these coefficients. As this is a non-parametric technique, it does not require the usual assumptions of normality associated with regression models.


Figure 5: Structural Model for Citibank

Figure 5 shows that the exogenous variables explained 43.4 percent of the variation in Information Quality, 48.9 percent in System Quality and 44.9 percent in Service Quality. Table 1 presents a summary of the hypotheses and findings. The table shows that neither one factor on Organisation Structure nor one factor from Organisation Culture was supported.

CONCLUSION

The primary objective of this study was to investigate the use of a structural equation model to investigate the impact of organisation structure and culture on Information Systems Success. To test the research hypotheses, partial least squares (PLS) analysis was used. Although the parameters are estimated together, the model was analysed and interpreted in two stages: (1) the assessment of the reliability and validity of the measurement model, and (2) the assessment of the structural model. Overall, there were partial support found for the structural model tested in this study. Neither one hypothesis for Organisation Structure nor one factor supported the hypothesis on Organisation Culture. The results were discussed in the context of Citibank which unearthed some important discoveries, primarily in the context of Citibank culture.

ABSTRACT

Information and Communication Technology (ICT) become more important nowadays. The Malaysia government has also define attractive policies to make our economy environment more attractive such as Multimedia Super Corridor which is emphasize the implementation of ICT in various economy sector and also to make ICT as an important agenda. This includes facilities management sector in Malaysia. Therefore, this research will be planned to build a national ICT Management Framework for facilities management sector in Malaysia. This framework is a strategy and synergistic combination of a number of key components, working in tandem. The framework is best viewed as an interconnected triangle consisting of three key elements, namely, people, infrastructure and applications. The ICT Management framework must identify the importance to innovation of building strong link between ICT and facilities management sector. These will enhance facilities management sector capability to produce and deliver globally competitive product and services, to facilitate growth.

INTRODUCTION

As the use of computers and telecommunications have changed over time, the portfolios of information systems suitable to an era of inward-focus automation of basic activities are unlikely to be suited to an age which focuses on information to support executive decision making, connect the organization to another organizations in the business environment. According to Konsynski and Tapscott, ICT is a factor in contemporary business environment to growth and as agent to link between two or more organizations with distinct and probably different structures, strategies, business process and organizational cultures.

The companies must take part and alert with new ICT system because to enter in globalization business, all the management system must be up date and all staff in the companies should know about ICT very well especially for the management.

All the companies in Malaysia must take action to build their company ICT system and there must have a good ICT framework. Framework is very important because framework is a collaborative community based effort in which these commonly needed data themes are developed, maintained, and integrated by organizations. Companies see the framework as a way to share resources, improve communications, and increase efficiency. Framework is best viewed as an interconnected triangle consisting of three key elements, namely people, infrastructure and applications.

Many types of organizations participate in developing and use the framework for their management. Although different organizations have characteristics data use pattern, all organizations need different resolutions of data at different times, particularly when they are working together. The framework represents a nationwide community for data sharing, and provides the benefits for the companies as a guideline to involve in globalization market.
Developing the ICT framework take a long time but, it is very important especially for facilities management in the companies. In Malaysia, facilities management still a relatively new concept, which makes it difficult to present a definitive description. Facilities management can be described as multifarious because of the diversity of its core component such as technical, financial, administrative and management skill.

The scopes of facilities management will depend mostly on the company of which it is a part. Some companies may consider that the facilities management department should manage all non-core activities. This could therefore

include departments such as purchasing, accounts, legal, and travel. Other companies may have their facilities management department incorporated into another support service function, such as finance or personnel.

Nowadays, facilities management has become a profession. Quite different from the role taken on by the engineer in the early eighties which was described by Becker "Facilities management resided in the boiler room not the boardroom" (Becker, 1990). Facilities management is important and the companies should take serious with facilities department.

The companies can manage their facilities management very well if they have a good system. For this situation, a framework is important to clearly for organize their company as a guideline and basic step to make any changes their process management to enter in era globalization.

MATERIALS

Information System Planning In The Modern Context

By the mid 1990's, it was arguably reasonably reasonably well established that some sort of formalized strategy information system planning was an appropriate undertaking for most organizations. Information system planning is to be closely allied to the organizations business planning activity, the accept wisdom at the time suggesting that ICT should only be attempt once a business strategy have been develop and articulate, and hence understanding reach of direction the organization planning to follow for the next few year, its goal, objectives, core business processes and its changes agenda, for examples. With this business strategy establish and share understanding reach among executives, an information system plan could be develop, determining the information and information system needs to support the business strategy, and thus guiding investment decision into the future.

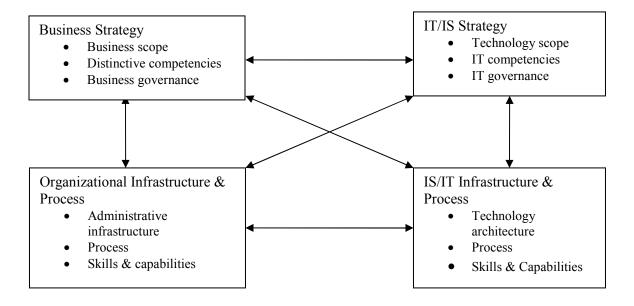
An interactive and generative process is envisaged, recognizing a general trend of establishing a business strategy, then an information system strategy, and finally information technology, but acknowledging the constraints and pressures in the real world which may act to limit the strategies somewhat. Given the rate of technology change, and the potential and impact that modern ICT could have directly on business strategy, and the outset o this process it is important to be aware of technological advances that may impact or alter the chosen or desire course for an organization (Peppard,1993;Liedtka,1998). The examples for the strategy framework it shows at Figure 1.


Figure 1 : Achieving Strategic Alignment (Adapted from Henderson and Venkatraman, 1994)

Rationale For Facilities Management

Most buildings represent substantial investments for organizations and usually have to accommodate and support a range of activities, taking into account competing needs. Within those activities is the organization core business, for which an appropriate environment must be created in buildings that may not have been designed for the purposes on organization might be on its core business, it cannot lose sight of the supporting services-the non-core business.

Company may have already considered the distinction between their core business and non-core business (such as cleaning and security) as part of the drive to deliver customer satisfaction and achieve better value for money. Since running costs account for a significant part of annual expenditure, there is bound to be pressure to look for savings in non-core business areas. Cutting operating budgets may be a financial expedient, but may not foster the company's long term development. Since the running of a company involve complex, co-ordinate process and activities, it is necessary to take an integrated view. A piecemeal approach to cutting costs in unlikely to produce the require savings and may impair the company's ability to deliver high-quality services.

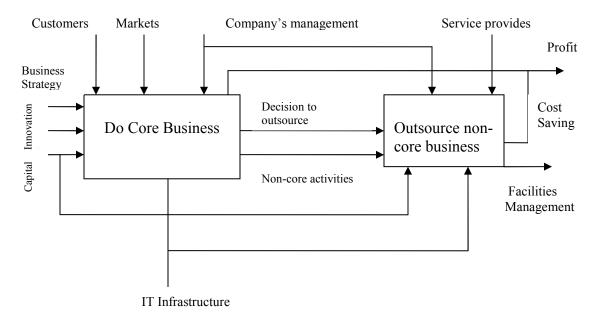
Facilities management can therefore be summarized as creating an environment that is conductive to carrying out the company's primary operations, taking an integrate view of the services infrastructure, and using this to deliver customer satisfaction and value for money through support for and enhancement of the core business. Facilities management also can describe as something that will sweat the assets, that is make them highly cost effective, enhance the company's culture and image, enable future change in the use of space, deliver effective and responsive services, and provide competitive advantage to the company's core business. Relationship between core and non-core business in company shows at Figure 2.


Figure 2: Basic Relationship Between Core And Non-Core Business

Company may not be aware of the extent to which value for money in facilities management can be improved. There are common themes and approaches to facilities management, regardless of the size and location of buildings, although these may not necessarily result in common solutions to problems. In some cases, estate-related and facilities services outsourced (contracted out) and in others retained in house for good reasons in each case. There are also many companies that operate what might be described as a mixed sourced in some measure as well as being retained in house.

Whichever course of action has been taken, the primary concern is the basis for the decision. Where the companies approach has been arrived at for entirely proper reasons, such as demonstrating better value for money from one approach as opposed to the other, facilities management is working effectively.

THE DEVELOPMENT OF ICT IN FACILITIES MANAGEMENT

The use of information technologies without the overarching direction of and information system, more often than not, leads to generation of voluminous, poorly focused and irrelevant information. The creation of excess information in this way is a good reminder of the need to evaluate an information system on the basis of a cost-benefit analysis.

The lack of information on products and components in terms of usage and cost can lead to difficulties in focusing the role of Facilities Management and establishing the supply chain within it. Difficulties in monitoring and tracking financial information can also prevent efficient budget control, accurate estimation of work, and contract and purchase management. Good planning in maintenance, operation and refurbishment can be hindered by the availability of life cycle information that is, for instance, crucial in the planning the replacement of components.

Currently, there are no standards that support information exchange and sharing across the building life cycle. Given that there is potential for improvement in business process though the exchange data on the facilities management process, there is a growing need to investigate the issues involve in developing a standard that can benefit this most important part of the business life cycle. This standard could then be use to assist in the development of an information management system to support the exchange of information and the assessment of facility requirements. Such an information system requires a large volume of data. Accurate assessment of a facility's needs requires knowledge of equipment standards from a design and construction information systems, access to accurate maintenance records and repair and replacement costs, access to operation and occupancy information, other operating costs, space management data, operation standards and data from occupational and health and safety information system and from a financial and commercial information system.

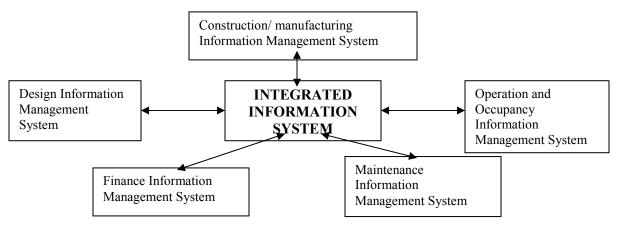
An integrated information system as shown in Figure 3 could assist facility managers and other project tem members to combine data and information on a facility's life cycle, and base on the integration of cost and commercial data, design and manufacturing and construction data together with facility operation and maintenance data.


Figure 3 : Integrated Information Management System

CONCEPTUAL FRAMEWORK

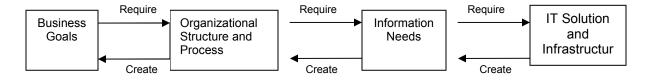
The overall conceptual framework that forms the basis of this pilot research project is shows at Figure 4.


Figure 4 : Sample of Conceptual Framework

This conceptual model hyphenise that information technology acts as both amenable (provides new possibilities for organizations to achieve business goals) as well as a source of innovation (emerging technology provides new possibilities for organizational structure and processes and may generate new business goals)

In addition, this model may influence organizations in at least three different ways:
1. Strategic positioning
    Information technology may provide a means for organizations to uniquely position themselves in the market place in a manner that would be impossible without the availability of information technology. Examples of strategic positioning are emerging in the form of 'virtual organizations' which provide substantially improved value to customers compared to traditional organizations. Strategic applications of information technology may involve inter-organizational information sharing, such as the use of distributed database.
2. Work group productivity
    Instead of affecting the entire organization, work group productivity effect subsets of an organization. The use of groupware (e.g., Internet collaborative applications) has the potential to empower and integrate project teams for substantial improvements in project productivity and at the same time reduce the need for middle management.
3. Process redesign
    Process redesign may affect the productivity of one or more individuals as jobs are reconfigured and processes simplified. Information technology can facilitate the task of process redesign by providing tools that eliminate routine jobs and decentralize decision-making.

CONCLUSION

As developing countries, face the new opportunities and challenges of the global network economy, there is increasing debate about how ICT can more effectively enable socioeconomic development. Although several countries have in fact created national ICT task forces and developed national ICT strategies, the lack of comprehensive frameworks to illustrate how to use and deploy ICT development leaves nations struggling to identify effective strategies, sometimes even pursuing detrimental and costly approaches.

Strategies for use the ICT are not universal. Countries face different circumstances, priorities and financial means and should therefore adopt different strategies accordingly. The framework can be help in determining a strategy regardless of what goals have been established, since coordinated action along the five areas identified in the framework is always likely to yield more effective results. However, the evidence and analysis presented suggest that strategy that focuses its ICT interventions towards the achievement to development goals is more likely to achieve marked socioeconomic development.

Facility management is essentially workplace management. In essence, it is a manifestation of facility management as the interface that manages changes in people, facilities and technology. They are many opportunities and expansion areas be it in properties, human resources, finance or ICT. Facilities management should have the ability to anticipate as to what organizations will require in future years. In the past, the role of facilities was merely that of service provider, and now, facilities management as a business solutions.

ABSTRACT

Business environment is paying increased attention for expert system technology to aid in decision making. Business Expert System (BES) is computer applications that provide decision support similar to that of human expert in solving problems. Through expert system (ES), rules can be associated to evaluate the conditions and determine the result. There are several areas in business that employed ES to help the business run more efficient and fast in decision making such as product availability, credit grades, security levels, document generation, insurance and many more. Nowadays there are many software and technologies that have been developed to help naïve developer to construct an ES for their business. This paper discusses these software and technologies and reveals the advantages of the ES in business and also its future prospect. This paper also discusses the challenges of implementing ES in business and the sign of new life in the rule-based system market, which suggest a coming upswing of interest.

INTRODUCTION

Business and its environment are more complex today than ever before and the trend is toward increasing complexity. The decision making process today is more complicated than it was in the past. Thus, experts are needed for advice when an organization faced with complex decision to make or a problem to be solved. These experts have specific knowledge and good experience in the problem area. In order to help decision maker, ES is essential because of its ability to mimic a human expert.

ES is a system that uses human knowledge captured in a computer to solve problems that ordinarily require human expertise (Turban & Aronson , 2001). The purpose of an ES is to capture the specialized knowledge and experience of experts and apply them to individual problems. This knowledge then stored and manipulated by the system to provide a specific advice, hint, explanation, conclusion and recommendation in reaction to input by users. ES can make inferences and arrive at a specific conclusion. Then, like a human consultant, it advices non experts and explains, if necessary, the logic behind the advice (Jackson, 1998). Extracting the relevant knowledge from the human expert is a critical task and usually will be done by a knowledge engineer, an individual who studies how human experts make decisions and translates the rules into terms that a computer can understand, and who will then build the ES knowledge base (Peter, 1998).

ES as one of the computerized support system is quickly gaining credibility in many organizations world wide. Within recent years, ES have been built and implemented for many business applications. At a slightly later time, business began to learn and experiment with the ES technology in order to build up an in-house capability for this advancing technology. ES will serve as a tool to improve the effectiveness and efficiency of selected business operations.

EXPERT SYSTEM IN BUSINESS

The growing number of successful applications of ES such as medical diagnosis (Sridhar & Kumaravel, 2002; Venkatachalam *et al*., 2002), environmental (Rahman *et al.*, 1999; Ta-oun *et al.*, 1999), agriculture (Tahir & Tanalol, 2002), engineering (Saad & Bolong*,* 2002), business and many other applications have prove the effectiveness and the efficiency of ES. In terms of business functional areas, ES has been and is continuing to be built in applications such as finance, accounting, marketing, contracting, strategic management, tax planning, insurance, fault isolation and others. A survey by Eom (1996) revealed that many ES have a profound impact, shrinking the time for tasks improved customer satisfaction, improved quality of products and services, and accurate and consistent decision making.

The ability to speed up the processing time and the accuracy of selection, make ES very effective in insurance organizations as the entire industry becomes increasingly more complex. For example, The Meiji Mutual Life

Insurance Company in Japan used Life Insurance Plan Selection ES to help them in order to overcome the problems faced by the company (Attar, 2003). The company found difficulties to ensure that all the insurance sales staff had the expertise and the latest knowledge required to provide the best advice and services to the customers. Attar (2003) has developed the ES so that when the details of a customer are entered, the system assesses the suitability of all plans and report on the best five suited to their needs and a justification for the choice.

Flory (1997) reveals some advantages of ES as decision tools in the performance of complex accounting tasks, like easy access of a comprehensive information storage system, uniformity and consistency in the performance of accounting functions and can solve actual accounting problems as well as to help train inexperienced accounting personnel. Boer and Livnat (1990), constructed ES to determine the accounting treatment for leases by the lessee. The system was used as a teaching aid. The students in one accounting class used the ES and textbook material, while another class used only the textbook material in solving problems pertaining to leases. The results indicated the students that used the ES made fewer errors in classifying leases as either capital or operating leases than did the students who used only textbook material.

Another business application that intended using ES is sales and marketing. For example, Elf-Atochem North America, the chemical manufacturers has been using ES to help people in sales and marketing (Attar, 2004). Atochem's sales people need to identify the best grades of product to meet precise technical specifications. Attar (2004) has developed Rilsan® Advisor, the ES that leads a series of questions about the customer's application by following decision trees that embody detailed expert knowledge about Atochem products. When the information about an application completed, it recommends grades to meet the needs. The system helps to reach high quality decisions for experienced sales people, while novices, the system act as a teacher who is expert in Atochem's products. Hence, gives them a set of guidelines that leads them away from choosing unsuitable products to start out a new application.

EXPERT SYSTEM FOR STRATEGIC MANAGEMENT

Expertise and experience are key factors for experts in strategic analysis in order to give advice on strategic matters such as the strength or the competitive position of an enterprise. ES may be able to do the same if this heuristic knowledge can be modeled and processed properly. Strategic analysis is one that is well documented and intricate, lending itself admirably to being modeled by an ES.

Applications Business System division of IBM has been using Business Insight, an ES for strategic management as a decision support tools to integrate both the qualitative and quantitative data that managers must take into account when planning strategy. According to McNeilly and Gessner (2003) from IBM Corporation, Business Insight presents a user with a strategic analysis, business observations, key factors influencing the business success, business strengths and weaknesses, and predictions for the success of different strategic options. From the user's response to questions posed by the system at input time, it can perform a range of analyses giving the user practical insight and advice on his business and marketing strategies. The system shows a trail of its logic for every comment or recommendation it makes.

According to Wierenga (1992), what makes these domains especially suited to knowledge-based reasoning, is the fact that many situations faced by marketing managers cannot be adequately represented by mathematical models, but instead rely on heuristic decision making. This, together with the extensive theoretical foundations of these domains have, makes ES on marketing problems potentially very strong, provided the expert's heuristic knowledge can be captured in the reasoning process (Arons *et al.,* 1998).

EXPERT SYSTEM DESIGN

Figure 1 shows the architecture that make up a typical ES for a particular problem domain. The architecture consists of two parts: the development environment and the consultation environment. According to Turban & Aronson (2001), the development environment is used by a knowledge engineer to build the components and put knowledge into the knowledge base, while the consultation environment is used by the end user to obtain expert knowledge and advice.

The user views and interacts with the system through a *user interface*. There are varieties of ES interfaces, including natural language, question-and-answer, menu driven or graphics. Somehow the best user interface is interfacing that user friendly.

Knowledge acquisition is the accumulation, transfer, and transformation of problem solving expertise from experts or documented knowledge sources to a computer program for constructing or expanding the knowledge base (Turban & Aronson, 2001). Among the sources of knowledge include human experts, end user, reports, books, regulations, database and web information. Knowledge acquisition is the "bottleneck" in the development of an ES because it remains the most difficult task to acquiring knowledge from expert (Turban & Aronson, 2001; Durkin, 1996; Tahir & Tanalol, 2002). This is so, since the acquisition of knowledge from human experts requires special skills and abilities by the knowledge engineers, as well as the application of techniques with an interdisciplinary character (Tzafestas & Tzafestas, 1997).

Figure 1: Architecture of an ES

The user views and interacts with the system through a *user interface*. There are varieties of ES interfaces, including natural language, question-and-answer, menu driven or graphics. Somehow the best user interface is interfacing that user friendly.

Knowledge acquisition is the accumulation, transfer, and transformation of problem solving expertise from experts or documented knowledge sources to a computer program for constructing or expanding the knowledge base (Turban & Aronson, 2001). Among the sources of knowledge include human experts, end user, reports, books, regulations, database and web information. Knowledge acquisition is the "bottleneck" in the development of an ES because it remains the most difficult task to acquiring knowledge from expert (Turban & Aronson, 2001; Durkin, 1996; Tahir & Tanalol, 2002). This is so, since the acquisition of knowledge from human experts requires special skills and abilities by the knowledge engineers, as well as the application of techniques with an interdisciplinary character (Tzafestas & Tzafestas, 1997).

The "heart" of ES is the *knowledge base* which contains the domain knowledge. It contains both facts and rules. Fact is general knowledge about the problem domain while rules or also known as production rule is formal way of representing knowledge in heuristic manner that direct the use of knowledge to solve a problems in particular domain. A rule consists of an IF (condition) and a THEN (action) part. Swamynathan & Geetha (2002) pointed that knowledge represented by the production rule is relevant to the line of reasoning being developed if the IF part of the rule is satisfied; consequently, the THEN part can be concluded, or its problem-solving action taken.

The *inference engine* is the "brain" of ES that models the process of human reasoning. According to Durkin (1996), this components act as processor for ES that matches the facts contained in the working memory with the domain knowledge contained in ibbc knowledge base and draw conclusions about the problem. It searches the rules for a match between their premises and information contained in the working memory. When the inference

engine finds a match, it adds the rule's conclusion to the working memory and continues to scan the rules looking for new matches.

During the consultation session, all the facts that are discovered will be stored in *working memory*. Working memory matches the information enters by a user with knowledge contained in the knowledge base to infer new facts. The ES then enters these new facts into the working memory and the matching process continues until the conclusion is reaches.

One way that makes the ES looks unique because of its *explanation facility*. With this facility, ES can provide an explanation to the user about *why* the question is being asked and *how* the conclusion is being reached. Users will feel more confident with the results and more comfortable to use the system.

Human element in Expert System

The main people involved in ES developers are expert, knowledge engineer and user. Each plays a key role in the development of the system (see Fig. 2).

The Expert

The domain expert is a person who provides the skill and knowledge to solve the problems that most people cannot solve with much efficiently. Expert can be referred as a person who has worked in the domain area, understands its problem-solving-techniques and has the special knowledge, judgment and skills that are not known or available to most people. The domain expert is responsible to provide their expertise and knowledge to the knowledge engineer about how he or she done the job. The knowledge then will be represented as rules in ES.

Knowledge Engineer

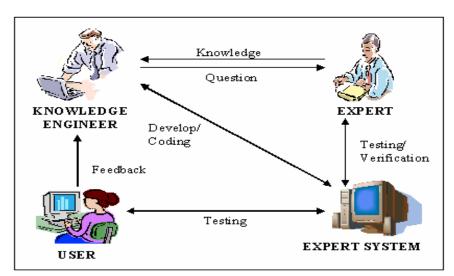
The knowledge engineer plays several roles during the ES development. Generally, his or her main task is to elicit the knowledge from domain expert and transform elicited knowledge into the ES. Among the responsibility carried out by knowledge engineer are helps the expert to articulate the necessary knowledge, structure the knowledge and problem solving methods in a right way that allows the ES to solve problem, select the suitable software package that can best represent the expert's knowledge and inference strategies, responsible for coding, testing and reviving the system and also maintaining the ES.


Figure 2: The Human Involved in Expert System

User

The end user is the individual who will use the system to assist them in making the decision. In most applications, acceptance of the system depends on how the system fulfills the requirements of the end user. Thus, the needs of the user must be considered throughout the design cycle of ES.

The development of Expert System

Like most artificial intelligence, building ES requires highly iterative process. Iterative here means a series of repeated actions (Awad & Ghaziri, 2004). Generally, work on the system begins with *domain identification phase*, where the world view or the potential of the ES has been examined. Figure 3 presents phases in ES development.

The next phase is to acquire the necessary knowledge on the problem that is used to guide the development effort. The process of acquiring knowledge from the expert is formally known as *knowledge acquisition*. This is done in initial interviews with the expert and by observing experts during the performance of their job. Next, knowledge engineer and expert begin the process of tracking the expert's problem solving knowledge. Once the knowledge engineer has obtained a general overview of the problem domain and gone through several problem-solving sessions with the expert, he or she is ready on begin actual design of system.

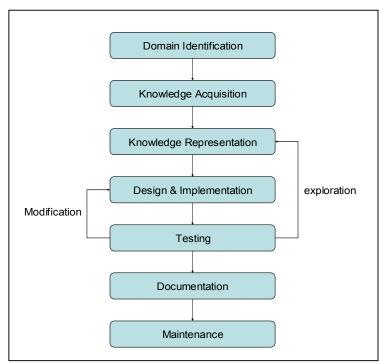
During the design phase, an initial prototype system is built. The purpose of the prototype is to provide a vehicle for obtaining a better understanding of the problem (Durkin, 1996). Once the prototype has been implemented, the knowledge engineer and domain expert *test* and refine its knowledge by giving it problems to solve and correcting its shortcomings (Luger, 2001).


Figure 3: Phases in ES development

Once the overall structure of the system and its knowledge validated, the next phase is *documentation*, where it explains how to operate the system and possibly provides a tutorial that steps through the major operational features of the system. After the documentation phase, the system is deployed in the work environment. Then, it will need to be periodically *maintained*, because an ES evolves over time. Experts are constantly training themselves on new situations; an ES must be adjusted for these cases. Therefore, it is important that an effective maintenance program be established for an ES project.

THE CHALLENGES AND FUTURE PROSPECT

Business decision making (BDM) has a major impact on the level of quality of enterprise's operation. The main field of the management of the BDM is presented by the economic treatment of decisions, which are based on various sorts and types of information i.e. factual and heuristic (Potocan, 2001). Business Expert System (BES) is computer applications that provide decision support similar to that of human expert in solving problems. Through ES, **rules** can be associated to evaluate the conditions and determine the result. BES can help the decision makers had a variety and flexible information in business decision making. Implementing ES in business is still challenging. The challenges and the way to overcome the challenges will be discussed in next section. The sections also open the other way to enhance the ES to be coming a powerful tool in business.

The Challenges

There are several areas in business that used ES to help the business run more efficient and fast in decision making such as product availability, credit grades, security levels, document generation, insurance and many more. Heather (2000) quoted McGraw, the vice president of corporate technology at Cigital saying that businesses must determine which software **characteristics** are most important to their success such as reliability, usability, functionality, security, performance, production time, safety and so on. This characteristic is reflected the characteristic of ES because in business there are lots of business rule such as the criteria for selecting the proposal, planned investment, price to be set, budget structure and many more that can be use as the knowledge based for ES. Even though business rule change, ES still can adapt easily to the changes. Now days there are many software and technologies that have been developed to help naïve developer to construct an ES for their business. There are SUMit ES technology, VP-Expert, Expert Valuation System, ES Language Technology, ES for Advertising Persuasion (ESAP) and so on.

According to Kamel (2002), the failure in implement any technology are associated with the nature of the decision maker such as unwillingness to spend time learning, preference to rely more on personal experience and intuition rather than information technology tools and techniques and resistance to changes. ES is not replacing humans but support their decisions (Trencher, 1998). The objective is to augment and thereby assist humans. For example, an insurance company have several conflicting objectives when processing claims because claims experience is a major element of overall customer service and therefore fundamentally affects customer satisfaction; the insurer wants to be as responsive and quick as possible in handling claims. Insurer recognizes that a high percentage of claims are legitimate and does not want to alienate its good-faith customers by subjecting them to needless delay and inconvenience. On the other hand, it is critically important to identify potentially fraudulent claims that require further scrutiny. ES can help in several areas such as below:-

- To identify the factors that the best claims examiners use and the patterns, relationships and thought processes involved in examining factors to determine whether a claim might be fraudulent.
- To devise a way to collect appropriate data at the time a claim is filed, where it enable a thorough examination of the claim.
- In looking for the proper patterns and relationships to provide insurers with an automated warning of possible fraud, while at the same time expediting the handling of claims with a low probability of fraud.

An interview survey by Vedder *et.al* (1999), the immediate problem for Mary Kay Cosmetic Company in implementing the ES is there is no one in the company knew how to maintain the ES. This is because after completion of the project, Mary Kay did not continue its relationship with the developer. It will be a problem for the design team to add new rules into the ES because no one was available to make the changes. This problem can be solved either make business relationship with the developer or give a training how to maintain the ES to the staff that involve in using it.

Time pressure which served as a controversial factor for some situations, it has been attributed a creativity stimulating potential, while in other cases the time deficit has been indicated to suppress creativity. In business, a tool that consumes little time and easy to use, leaving more time for high-value managerial management activities are needed for creative problem analysis and decision development (Skyrius, 2002). For example, management at Mary Kay Cosmetics develop an ES to assist with the selection of packaging materials for cosmetic products based on marketing requirements and chemical composition of the product. The use of ES greatly simplified the organization and sequencing of the package decision process, thus **saving time** (with fewer and shorter meetings) and effort (spent on redesigns) (Vedder, 1999). Furthermore, the ES automated package/product compatibility, as well as some technical and cost feasibility issues. It's greatly speeded the entire decision process, saving approximately four weeks.

The Future of ES

ES can be more powerful tool if it's combining with other artificial intelligence techniques such as Fuzzy Logic (FL), Intelligent Agents (IA), Neural Network (NN) and many more. An accurate market intelligence and effective decision making is an essential for quicker access to information on their business, markets, customers, suppliers and distributors. This is leveraging competitive advantage for their business. According to Al-Sharouf and James (2004), the emergence of **software agent** technology, will give a supporting mechanism for enabling new trends in e-business. The agent is software that helps delegates in making decisions and also known as Intelligent Decision Support System (IDSS). They focus in building a statistical testing approach for testing multi-bidding e-commerce. The future direction is on address how and when to apply statistical approaches using software agents.

Cheng (2002) proposed an **intelligent agent-based** system that is capable of recommending optimal products based on the customer's current preferences obtained form the iterative system-customer interactions. The system is to recommend products that best satisfy the consumers current needs and with the optimal quality. The system use the ephemeral information provided by a consumer at the time they consulting the system for suggestions and the built-in expert knowledge about the products to look for the optimal ones. This decision making method is only used to recommend optimal notebook computers and home theatre systems. For future prospect, Cheng proposed whether this approach can be used for other products, especially for the products with more features such as digital cameras.

ES for e-business metrics with emphasis more on the data gathering and knowledge acquisition strategies were been build (Swamynathan and Geetha, 2002). The system generates rules using the induction learning algorithm and maps it to the JESS ES shell script. The ES gives a reports and expert opinion from data warehouse are very useful in decision making performance. However this system can be enhanced to include fully noisy data and totally random data by using FL. FL can be use to classify unknown and totally random data set into some useful production rule without adversely affecting the over all inference rules. FL is concerned with the reasoning about 'Fuzzy' events or concepts. Example of fuzzy concepts is 'salary is high'. When salary is high, at RM 8000 per month, RM 9000 per month or RM 10,000 per month? If we define the threshold of high salary at RM 9,000, then the implication is that a salary RM 8,999.99 is not high. When humans reason with terms such as 'high' they do not normally have a fixed threshold in mind but a smooth fuzzy definition. Humans can reason very effectively with such fuzzy definitions, therefore, in order to capture human fuzzy reasoning we need FL.

Other future prospect, ES in business can implement hybrid technologies to enhance the abilities of the system. According to Ariffin *et al.,* (2004), the combination ES, NN, FL and Natural Language Processing (NLP) can assured adaptability, personalization as well as user-friendly for the knowledge management system. ES is used to be the knowledge-based repository, where it is important to comprise a good data repository. NN is a model that mimics to human neuron system that ability in manipulates and learns from the set of input or information, where it used to utilize the previous sets of data and cases in order to predict or forecast the similar situation in future. Usage of NLP in knowledge management system will make the system owns the ability in understanding the natural human languages. This will provide the workers with additional elements like dictionary, interactive glossary module and machine translator. However there are further researches in making sure whether their hybrid methodology is possible and practically implemented.

DISCUSSION

This paper revealed the important of ES in business either in Decision Making System or Knowledge Management System. From the survey there are many papers that discussed the usage of ES in business for superior and successful company. The advantages of ES show that there are lots of potential on implementing ES in the business areas. The potential of ES in business are:-

- Performance – ES do not forget, but human does. By using ES in business the basic decision making suppose to be clearly not having a mistake.
- Reproducibility - Many copies of an ES can be made but to train new human experts is time-consuming and expensive.
- Efficiency – can increase throughput and decrease personnel costs such as ES not inexpensive to operate, much cheaper than paying the human expert and saving in wages (by eliminating a clerk).
- Consistency – ES similar transactions handled in the same way but human can be bias.
- Timeless – information will always be there when ever we need for decision making.
- Knowledgeable – The knowledge of multiple human experts can be combined to give a system more breath then a single person is likely to achieve.

ES can be more powerful when it has been combined with other artificial intelligence techniques such as Fuzzy Logic, Neural network, Natural Processing Language and many more. The combination will overcome the disadvantages of ES.

CONCLUSION

ES is well known in business as a system that improves company decision's making, knowledge management and strategic management. However the popularity of ES is drop off due of certain factors such as human perception, didn't have the sensory experience, didn't have common sense and not suitable for complex decision making.

Researches on ES are still active and will continue with some modest expansion. The most prominent companies today are CleverPath Aion (CA) (with Aion/Cleverpath), Fair Issac with Blaze Advisor, ILOG and Pegasystems.

There are three signs of new life in the rule-based systems market, which suggest a coming upswing of interest. Firstly, there is an increasing interest in business process management (BPM). Rule-based systems are not the same as BPM systems - they are business process *automation* systems - they are being suggested for use in the BPM context to help to support, automate or enforce processes across business functions. Pegasystems now describes itself as a BPM company, and companies such as Staffware and FileNet have partnerships with rule-based system companies

Secondly, conferences are on the rise for academics and for businesses, such as the RULE series of international conferences on rule-based programming sponsored by the Association for Computing Machinery (ACM), and European Business Rules Conference, Zurich.

And finally, there is a new three-letter acronym - the BRE or business rules engine. CA is the only company to explicitly adopt this in its nomenclature so far, but it always helps in the IT industry to have a buzzword or phrase similar to Enterprise Resource Planning (ERP), Customer Relationship Management (CRM) or Online Analytical Processing (OLAP).

Although the popularities of ES is decline due of certain factors, ES still can be the best decision making tool in business if the ES combine with others intelligent techniques. Furthermore, the developer and the company should take a serious action in representing the knowledge into the system for better ES.

Information Technology and How It Can Improve the Muslims in the Field of Education

Norazlina Zainul
Department of Information System,
Faculty of Information & Communication Technology,
International Islamic University Malaysia,
53100 Kuala Lumpur, Malaysia.
E-mail: Norazlinaz@Iiu.Edu.My

ABSTRACT

Information technology (IT) is an area that has affected all our lives in one way or another since the late 20th century. This technology has rapidly changed the world to the point where we now feel that we live in a much smaller place. These IT developments, especially the Internet, have brought people closer together despite the distances between them. Muslims should accept the challenge and use it to the greater benefit of the Islamic community at large. In their desire not to tarnish the image of Islam, Muslims should be careful not to behave in such an extremely conservative manner as to leave a gap within the Muslim communities of the world. This research is targeted at identifying ways in which IT can bring a benefit to the ummah in general and more specifically to enhance the area of Education. This can be divided into distance learning (online course), da'wah and islaah, fatwa online, translation of Quran and Hadiths, information, Islamic software development, and sermons (khutbah). In Malaysia, some of the schools have been equipped with computers for the school children to have the exposure in using technology. Another example, the New Straits Times website has a section in education for even the preschool children, primary and secondary schools' students, and up to tertiary education. This research concluded by promoting the use of IT in the field of Education. Thus, the quality of learning for the Muslims can be improved. IT can help to invite others to know more about Islam.

INTRODUCTION

Objective

This research objective is to explore the possibilities of Information Technology to improve the Muslim ummah in the area of education.

Methodology

This research will be based on secondary sources such as articles, journals, books, Internet, etc. From these sources, then it will formulate the important points as put forward by scholars and IT professionals on how Information Technology can be used as a tool to improve the ummah.

Muslim Ummah

What is meant by Muslim ummah is there will always be a group of righteous people on Earth. The Muslims as a whole are the ummah that unites around the *Qur'an* (Holy Book) and *Sunnah* (act of the Prophet Muhammad SAW). They carried out the basic Islamic duties, believed in the principles of faith, and subscribed to Islamic moral values. The Muslim ummah will never be devoid of righteous people. Most Muslims adhered to the fundamentals of Islam and admitted that there is no God but Allah and that Muhammad SAW is the Messenger of Allah. The Arabic word for nation, "ummah", is employed in the Qur'an with many different meanings. The Arabic scholar al-Fayruzabadi mentioned ten different meanings for the word, which some of them are:
1. "A leader or example for others". Allah said: "Ibrahim (Abraham) was indeed a devout model of behavior (ummah), pure in faith and not of the polytheists" [Surah al-Nahl: 120]. This is the way the majority of the classical commentators interpreted this verse. Alternatively, the word "ummah" in this verse could be interpreted as "nation", meaning that he was a nation unto himself, since he was at one time the only believer on the face of the earth.

2. "An era of time". Allah said: "Of the two, the one who had been released remembered him after a period of time (ummah)" [Surah Yusuf: 45]. Likewise, He said: "If We delay for them their punishment until a specified term (ummah), they will ask: "What kept it back?"" [Surah Hud: 8].

3. A mode of thinking or an approach to life, whether correct or false. Allah said: "Nay! They said: "We found our forefathers following a certain way (ummah), and we will guide ourselves by their footsteps". Likewise, whenever We sent a warner to any people before your time, the wealthy among them would say: "We found our fathers following a certain way, and we will follow in their footsteps"" [Surah al-Zukhruf: 22-23].

4. "A group of people", however small. Allah said: "And when he arrived at the watering place in Madyan, he found there a group of men (ummah) watering their flocks" [Surah al-Qasas: 23]. Allah also said: "Every time a new group (ummah) enters, it curses its sister group" [Surah al-A'raf: 38].

Information Technology (IT) could be applied to improve the Muslim ummah in the area of economy or market, social, political, education, and much more. This research strongly suggested in applying Information Technology (IT) in the area of Education, which can be divided into Da'wah and Islaah, Software, Electronic, and Ijtihad. This paper explored on how IT could bring improvement to the ummah and to promote Islam to the world.

INFORMATION TECHNOLOGY IN ISLAMIC PERSPECTIVE

Islam did not against the development or enhancement of technology. Islam concerned with the problems faced by mankind, and Islam also encouraged Muslims to develop themselves, so that they could benefit the ummah. "It deals with all aspects of man's economic and political but always in the framework of total human development" [Z. Kausar].

Even though Islam encouraged its followers to seek prosperity and cope with the technology, Islam also laid some foundations that must be followed. If these foundations abandoned, then Muslims might lose in pursuing the worldly life. Despite of seeking progress, Islam concerned with effects on moral and faith. Therefore Islam has laid some philosophical foundations for development.

"The Philosophical foundations of the Islamic approach to development are as follows:
1. Tawhid (God's unity and sovereignty). This laid down the rules of God-man and man-man relationships.
2. Rububiyyah (divine arrangements for nourishment, sustenance and directing things towards their perfection). This is the fundamental, law of the universe, which threw light on the divine model for the useful development of resources and their mutual support and sharing. It is in the context of this divine arrangement that human efforts took place.
3. Khilafah (man's role as God vicegerent on earth). This defined man's status and role specifying the responsibilities of man as such, of a Muslim ummah as the repository of this khilafah. From this followed the unique Islamic concept of man's trusteeship, moral, political and economic, and the principles of social organization.
4. Tazkiyah (purification plus growth). The mission of all the prophets of God was to perform the tazkiyah of man with God, with man, with natural environment, with society and with state" [Z. Kausar].

Islam encouraged its followers to seek knowledge and mastered it, so that they could teach and inform others. Information technology is a very interactive means of sending information because it integrated audio, motion, and globally connected. If Muslim could take this chance to learn about IT, they could widely spread Islam all over the world. Through the Internet, distance is no longer a barrier for ending information.

Al-Afghani stated "if a community did not have a philosophy, and all the individuals of that community were learned in the sciences with particular subjects, those sciences could not last in that community for a century. The Ottoman government and the Khedivate of Egypt have been opening schools for teaching of the new sciences for a period of sixty years, and they are yet to receive any benefit from those sciences" [Z. Kausar].

Al-Qur'an and Information Technology

There are many verses in the Holy Qur'an that could be used as guidance for Muslims to understand Islamic opinion about world development or technology enhancement. Some are listed below:
- "Truly, successful is one who causes his self to grow in purity" [Al Qur'an, 91:9].
- "And seek, with the wealth that God has given you, the abode of the Hereafter, but do not forget your share in this world. And do good (to others) as God has done good to you, and spread not mischief, for God does not like those who do mischief" [Al Qur'an, 28:77].
- "Say: Travel through the earth and see was the end of those before you" [Al Qur'an: 30:42].

-       "We (Allah) revealed (Our Will) to him (Nuh) saying: Build an ark under our watchful eye, according to Our guidance and Our inspiration!" [Al Qur'an, 23:27].

The Hadiths and Information Technology

Here is some of the Holy Prophet's SAW saying which could be used as guidance for Muslims in understanding Islamic view about IT:

-       "Earning a lawful livelihood is obligatory upon every Muslims" [Suyuti, al-Jami'al-Saghir].
-       "A man has not earned better income than that which is from his own effort" [Sunan Ibn Majah].
-       "Seek the bounty of God and be not a burden on others".
-       "He who seeks the world lawfully, to refrain from begging, to cater for his family, and to be kind to his neighbor, will meet God with his face shinning like the full moon" [Mishkat].

EDUCATION

Educational Technology is a term widely used in the field of education (and other areas), but it is often used with different meanings. For example, it could be meant by hardware, which is a device to deliver information and serve as tools to accomplish a task. Hence, educational technology referred to a particular approach to achieving the ends of education. Instructional technology referred to the use of such technological processes specifically for teaching and learning. The evolution of multimedia has significant and positive impacts in the concept of da'wah (invitation towards Allah). Apart from extensive usage in the education, entertainment and business fields', multimedia titles could also be used to spread Islamic teachings.

There are growing numbers of multimedia CD-ROMs that carried various Islamic topics such as prayer presentation, interactive, video hajj presentation, and Qur'an translations in various languages, together with Hadiths, history of the Prophets, Islamic history and Muslim contribution to the world. Coupled with multimedia features (such as text, sound graphics, picture, video and animation) for interactive environment. The aim is to provide both Muslims and non-Muslims with an informative, unique and exciting way to learning Islam. An example of such application is multimedia CD-ROMs titled "Sign of The Creator" by Harun Yahya.

Distance learning [Online Islamic courses

It enabled students to study in a faraway country without really having to be physically there. An example would be an Iranian student residing in Iran, but studying an American degree in an American institution. Current information technology (online streaming and advanced web cam technology) allowed video-conferencing over long distances. Therefore a student thousands of miles away could still participate with the course. This is an advantage for Muslims because they (or their parents) fear that the western environment and culture would affect the students.

Another issue is on paying the tuition fees, and expenses of a place where there is a high cost of living such as studying in the UK. There are other issues of racism and social bias that could be avoided, and this is an advantage for the women who strictly enforced the principles of covering the "aurah" are followed. This way a person could benefit from a good education from the USA or UK for example, but still remained committed to Islamic morals and teachings. In addition, it could save the costs of accommodation and living in the advance countries where the cost of living are much higher.

Moreover, there are other educational facilities such as, online Islamic digital libraries (www.academicinfo.net/Islamlibrary.html) that have links to other sites and offered quality reading in the world. A lot of interests have been expressed in teaching Muslims about the astronomy of Islam, which include the timings of the prayers and how to determine other important events of Islam.

Da'wah and Islaah

"Da'wah" is the best way to spread Islam and increased the community of Muslim ummah in the world. "Da'wah means an invitation. In the Islamic context it means an invitation to Islam. Therefore Da'wah means conveying the message of Islam to Non-Muslim and inviting them to Islam, while "Islaah" means to improve,

correct, rectify or repair. In Islamic terminology, "Islaah" means correcting a Muslim or providing more knowledge of Islam to a Muslim" [Dr. Zakir Naik].

Based on the above definition, Da'wah is possible to be done to invite others to learn about Islam. However, basic knowledge and good understanding of Islam are necessary in order to spread Islam. In the modern era, Da'wah could be done in many ways, and application of IT played an important role in Da'wah such as electronic media, broadcasting media, print media, Internet and other media.

a. *Forms of Da'wah*

According to Dr. Zakir Naik, there are two forms of Da'wah:
1. Live and direct without any media. In this term Da'wah is done directly, face-to-face or without any interface. The message of Islam could be brought forward to Non-Muslim directly regardless the time and places.
2. Indirect through means of media. IT played an important role in indirect Da'wah; IT tools are used in this form of Da'wah.

b. *Different Media of Da'wah*

There are many medias that could be used for Da'wah. Dr. Zakir Naik in his "Forms of Da'wah" divided the medias into four categories:
1. Print Media
2. Audio
3. Video
4. Electronic Media

Firstly is print media. Print Media is a media that provided articles to the public. Print media could be classified into non-periodical and periodical. Non-periodical print media consisted of literature such as pamphlets, booklets, books, and more. Periodical print media consisted of newspapers, magazines, which are published periodically, either daily, weekly, monthly, annually, etc. Islamic literatures, magazines could be easily found today and they provided articles about Islam.

Secondly is audio. Audio is a media that provided a sound. Audiocassettes, audio compact discs, and digital audiotapes are the most popular audio media. The advantage of audio media is it could be heard anywhere, anytime such as at home, in the vehicle while traveling and walking or moving to the other places with the help of portable audio equipment. It also could be heard by a lot of people through radio broadcast.

Thirdly is video. Video is an audiovisual media or a media that provided sound and picture. The most popular video media are videocassettes, video compact discs (VCD) and digital video discs (DVD). It could also be shown to the public through cable TV networks, TV stations and satellite TV channels.

Fourthly is electronic media. Electronic media or computer media is another media, which could be used to do Da'wah and Islaah. Internet is used to convey messages and improve Muslim ummah. Now, there are many Islamic websites such as www.islamonline.net, www.islam.com, which provided forum discussion, chatting, and mailing list in order to get the latest information. It is very useful and the easiest way to do Da'wah, Islaah, and to know more about Islam. It will have an impact on the ummah to improve one's knowledge and practices to be a good Muslim. Electronic media could be stored on hard discs, diskettes, CD ROMs and DVD.

The Internet also facilitated the propagation of Islam. There are materials available in a variety of languages on the web, which are published by individuals and organisations. Many scholars put their ideas on the web so people could learn the thoughts of (and be influenced by) "scholars" who lived thousands miles away, besides listening to their local imam (scholars) [Gary Bunt].

Newsgroups could be used as a tool of Da'wah; which non-Muslims often contribute to the posts. They asked questions or voiced their comments to the Muslims. This is a chance to give Da'wah and dissolved misconceptions and prejudices. Anonymity of the Internet allowed those who might otherwise not approach Muslims the chance to interact and learn about Islam [Abdullah Al-Wassiti].

Fatwa on-line

"On-line fatwa" is one of the developments of networking. Fatwa that are subjected to database searched for a particular keyword or topic. Individuals could access to variety of websites, and search from the archives, which relate to one interest and field. For examples, IANA website and Fatwa Online provided archive of religious opinions on various issues. Surfers are allowed to send questions that they felt doubt with, and the scholars will response to them [Gary Bunt].

Islam Online is the only one of the Muslim web page, which is professionally produced and used the latest web technology, in Arabic and English. Its technology is produced and maintained by the same group of companies that also moved Al-Jazeera Satellite Television online in Arabic. It provided a daily selection of international news and interest to Muslims with wide range of advices from formal fatwa issued by the scholars in response to psychological counseling focused less on behavior than on psychology. This site, and others similar to it, also offered composed lessons, hadiths interpretation, scripture and other pronouncements.

Translation of Qur'an and Hadiths

Numerous versions of the translations of the Qur'an could be found, linked into diverse explanation and other materials. A good example is the website produced by Harf Information Technology, which adopted the multimedia aspects on the Internet to allow recitations to be played together with Arabic texts, English translations, and high-quality recitations. Beside the Holy Qur'an, most of the famous Hadith books also translated into English.

Information

New types of information technology such as the Internet and CD-ROM could be used to enhance courses in colleges and universities. Information Technology could improve Muslim ummah in term of knowledge. Education is the key to success. Every mankind should seek knowledge for improvement. It is supported by hadiths of Prophet SAW which one of them is, "Seeking knowledge is obligatory to all Muslim man and women". This showed that education is very important for everyone. Through IT, education could be spread widely for easy learning. There is no limit in gaining information. Beside IT could increase the knowledge on Muslims; it could also uphold the Muslims to become an educated ummah.

In the USA computers are used extensively not only by the adults but also by the children who learnt most of the Islamic rituals and knowledge through computer programs such as ALIM, AL-USTADH and AL-QARI. The use of ICT in general could benefit Muslim children, for example, Islamic computer programs available locally to enhance the teaching at the Madrassa (school) [Prof. S. Rogerson and M. M. Begg].

A large number of Islamic books and articles are also available for free including areas of belief, Islamic jurisprudence, guidelines on the Islamic morals and character, selected supplications, comparative religions studies and material for non-Muslims, Islamic magazines, Islamic history, information about almost all Muslim countries, websites with news services on the Muslim world [Gary Bunt].

According to Prof. S. Rogerson and M. M. Begg, IT skills are now an obligatory skill for life besides the numeric and literacy skills. "Indeed the Imams (scholars) too should be IT literate if they are to function to their full capacity. In addition to giving answers to questions in person, they ought to be able to reply to email questions from people who may be at the other side of the world. Islam is portrayed as a global religion, it will therefore demand global Imams – only the new technologies can provide such a capacity when positively used and without disregarding the social responsibility issues that have arisen through the computing revolution".

To place a computer in every mosque, able to unite the ummah through virtual communication among all the Muslims all over the world. This cyber mosque could be an accurate reference to the Islamic ummah and sources of new activities and current issues about Muslim. This would give opportunity for people to exchange opinion through cyber mosque.

Islamic Software Development

Another area in which IT could improve Muslim ummah is the development of software. There are lots of Muslims who have the intellectual capabilities to develop software. Now OIC (Organization of Islamic

Countries) has set up a committee called COMSTECH (Standing Committee on Scientific and Technological Co-operation) to promote scientific and technological corporation among its 57 member countries. Any organization involved in an effort to improve and strengthen the state of science and technology within the Muslim world faced gigantic challenges. COMSTECH has undertaken a large number of important programs to meet these challenges [Professor Ata-Ur-Rahman]. Software could be developed for academic, business, and other purposes. Such programs should include Islamic and ethical principals. For example, software to calculate Zakat (tax) payment for a business. This may be useful for both the zakat payer and the collector as it could save the time in calculating the zakat.

Harf Information Technology is a company that applied e-commerce for their business in providing Islamic software products. In order to see its products, log on to www.harf.com. There are many Islamic software products that are provided by Harf Information Technology, which some of them are Alfazh Al-Qur'an and Al-Mushaf (for desktop publishing).

Alfazh Al-Qur'an is a program that is used to memorize the Holy Qur'an and to learn the correct recitation. This program also taught the pronunciation of Arabic sounds and the recitation rules. This advance educational method helped one to memorize the Holy Qur'an by listening to it and repeating after the tutor. This program has two sections, which are the educational section and the practice section. The educational section taught us the Arabic alphabet, with different vowel marks, the pronunciation, the rules of recitation, and provided exercises and tests for evaluation. The practice section displayed the Qur'anic text and highlighting the recited verse and the letters that have special rules of recitation, so one could memorize the Holy Qur'an verse by verse. Translations of the meaning of the Holy Qur'an are available in Arabic, English, German, Indonesian, Turkish, French, and Malay. This program runs under Windows 95, 98, 2000.

Al Mushaf (for desktop publishing) is a program that allowed one to add Qur'anic text to mail message, and personal document to be printed out. It has many abilities such as to add Tafsir of Al-Jalalain below the copied verse or as a footnote, to insert the translation, control the format and fonts of the informatics text services, and to identify (color) different Qur'anic text recitation Waqf signs, "Allah" words, Sugda and Hezb signs. This program runs under Windows Arabized and 2000.

Beside Islamic software products, Harf Information Technology, which started in 1985, also developed great Islamic materials on electronic media. One of them is The Holy Qur'an Digital Book.

The Holy Qur'an Digital Book used the voice of Saikh Abdul-Rahman Al-Sudeis and Saikh Saud Al-Shureim who are the Imam of Al-Haram Mosque in Mecca. The Holy Qur'an Digital Book intended to help students, beginners, and non-Arabs to learn the Arabic language and the Qur'an through listening to the recitation and reading the instant Arabic text. This Digital Book is compact size and portable. It provided the user with convenient listening with the help of the sensitive audio feature. Other features in The Holy Qur'an Digital Book (from Harf Information Technology) are:

- LCD (Liquid-Crystal Display) in Arabic.
- Online audio-visual display.
- Easy search for Surahs and verses.
- Repetition of the required sentence for easy memorizing.
- Index of Surah names.
- FB and FF buttons for rewind and forward.
- Pause and replay functions.
- Book marking of Surahs and verses that will be saved even after shutdown.
- Usable at night through background light.
- Pocket size.

The specifications of The Holy Qur'an Digital Book are:
- Size: 107.5 mm x 68 mm x 16.3 mm.
- Weight: 105 gm. (including batteries).
- Power: DC 3 V.
- Batteries: 2 x AAA.
- Speakers: 5MW for right and left speakers.
- Frequency: 20 Hz - 20 kHz.

There is another website that also provided Islamic materials in electronic media. In order to see its products, log on to www.islamicbookstore.com, this is the Internet's largest Islamic store. One of its products is Al Hilal (wallet-size digital qibla compass, prayer time, calendar and calculator).

Al Hilal provided digital qibla compass functionality, prayer times for over 250 cities of the world, calculator feature, and more. Al Hilal is built in small size, sleek compact case portable so that fit into the pocket, or wallet.

The features of Al Hilal are:
- Qibla direction indicator for 250 cities worldwide.
- An automatic alarm for the five prayer times for 250 cities worldwide.
- Local time for 250 cities worldwide.
- Convenient calendar.
- Useful calculator.
- 5 local methods by region, Shafie and Hanafi.
- Daylight savings time.

QIBLA.
- Press the QIBLA key.
- The direction of Mecca will be displayed on the screen.
- The arrow at the bottom of the screen indicates the direction of Mecca

SALAT
- Every prayer time, Al Hilal will ring the alarm automatically and display the prayer time on the screen.
- Press the SALAT key.
- View the upcoming or previous prayer times by pressing the salat keys.

SPECIFICATION
- Display: Dot Matrix LCD.
- Size: 88 * 59 * 7.7 mm.
- Weight: 36g (including battery).

With the help of Al Hilal, one could easily know where the Qibla is and the prayer times regardless the time and places. It is easy to bring and useful when traveling.

Ijtihad

In his book G. Bunt, discussed about decision-making issues in Islamic context. A number of interviewees' showed people believed that the Internet (and related technology) could be the greatest force of any innovation or social change on Muslims during the next few decades. According to an interviewee at the International Islamic University in Islamabad, the development of IT technology allowed people to make ijtihad much easier. In other word, ijtihad is to find independent judgment based on the Islamic sources. By typing the keyboard, a lot of information on certain issues could be accessed. Even though the technology helped in making decision, without using the human's mind, ijtihad could not be done. However it is visible that modern devices made ijtihad much easier and especially with email, for example, it is easier to verify the findings with any scholars who lived in other parts of the world [G. Bunt].

Sermons (Khutbah)

There are large amount of sermons available online which these are one of the transformational qualities of the Internet on Muslims. Some of them prepared for local (for example, Tanzeem-e-Islami Pakistan), while others for international audiences (for example, Taliban, Khutbah Online, and Al-Muhajiroun). They presented a selection of recorded sermons to be downloaded.

With the present technological limitations, to download a sermon is time consuming since the file is huge. In the future, "when technology (including bandwidth) improves to allow a surfer to rapidly listen to and view sermons and other information "on demand"; not just through a computer, but by digital television or WAP telephone" [Gary Bunt].

RESULTS AND DISCUSSION

IT could improve the Muslim Ummah in wide areas such as Education, Social, Economic, and Political. For this research purpose it covered how IT could improve the Ummah in the field of Education. Education is

divided into Distance learning, Da'wah and Islaah, Fatwa online, Translation of Qur'an and Hadiths, Information, Islam development software, Ijtihad, and Sermons.

Firstly, IT made possible to conduct distance learning with video conferencing. Thus people could get oversea education without being there physically. This way, it could save time and cost. Secondly, with IT, it is possible to make da'wah and islaah. Da'wah is to invite others to learn about Islam, while islaah is to improve one practices, and knowledge of Islam. Moreover, one of IT products is Internet. It is possible now to get fatwa online and advices from scholars. One example is Islam Online where people all over the world seek scholars' advices to their problems.

Lastly, the advancement of Internet, CD ROMs, and software made possible for Qur'an and hadiths to be translated into many languages, to get the latest information such as news, to adopt cyber mosque, to make ijtihad, which is decision-making, and sermons or khutbah. Software produced by Harf Information Technology Company provides people such as to recite and learn Qur'an, to know the Qibla direction, Islamic calendar, calculator, prayer time, and more.

CONCLUSION

In conclusion, IT leads the improvement of the Ummah through Education. People all over the world could gain knowledge and information about Islam through print media, audio, video, electronic, and Internet. Education is divided into Distance learning, Da'wah and Islaah, Fatwa online, Translation of Qur'an and Hadiths, Information, Islam development software, Ijtihad, and Sermons.

In the holy Qur'an cited, "And spend of your substance in the cause of Allah, and make not your own hands contribute to (your) destruction: but do good, for Allah loveth those who do good" [Surah al-Baqarah: 195].

Software and Innovation: Analysis of the Task-Technology Fit Theory and Small Business as End User of Accounting Software Application

Rohaya Mohd Nor
Faculty of Economics and Business
University Malaysia Sarawak
94300 Kota Samarahan, Sarawak, Malaysia
E-mail: mnrohaya@feb.unimas.my

ABSTRACT

This paper attempts to explore the usage of the accounting software packages for small business application from the perspectives of the end user. The ultimate objective of this paper is to investigate the data entry task, in which constitutes a higher proportion of usage of the accounting software packages targeted for small business. Within the Theory of Technology-Task Fit (TTF), this paper raises an argument that the embedded design of software navigation for data entry task will affect the quality of the task performance. Further, this will contribute to the quality of user experience. Based on the finding of the selected software, this research proposes an innovative way of embedded design of software navigation for the data entry has to be one of the importance attributes for small business decision-making adoptions of the accounting software packages. And for the entrepreneurs of the accounting software packages, an innovative way of designing the software navigation for data entry can be an important determinant to differentiate their products quality with the competitors. The entrepreneurs or the software creators of the accounting software packages thus should not neglect the innovation part of designing the software navigation for the data entry tasks.

INTRODUCTION

Computing application has become an integral part of the daily business operations. For small business, one of the motivators for adoption is the ability of the computing application in handling the business financial and accounting transactions. Specifically, the accounting software or system package is useful and perceived as importance by small business for the needs to shift from the manual process of recording the financial or the accounting transactions to a more systematic, automated and better approach towards record keeping and management. Small business as end user of the computing application nowadays are becoming more sensitive and demanding in the process of acquiring the accounting software packages for business used. Griese and Kurpicz (1985) in their survey reported that the user convenience of the software, software flexibility and software performance are the three most frequently features mentioned by the small medium business as part of the criteria in their decision making process of purchasing data processing system. Chau (1995), in examining the factors that influence small business in purchasing software package reported differences of views in software selection between the business owner and the managers. For instance, the owners viewed software technicality much more importance than the non-technical side in comparison to the managers. The managers considered the price and the popularity among the most important criteria, while the owners considered those attributes as least important. Further, Nazem (1990) found that the majority of small business opted for off-the-shelf software packages and they are heavily utilized the software standard modules such as General Ledger (GL), Account Payable (AP), Account Receivable (AR) and Payroll Applications. Interestingly, their study also indicated that small business who used off-the-shelf package do not appear to be overly emphasized on the security. Ismail et al (2001) also found heavy utilizations of GL, AP, AR and Payroll in their survey on the northern region of Peninsular Malaysia among the SMEs. The majority (52.8%) of the respondents used combination of manual and computerized accounting systems, while fully computerized systems used accounted only for 33.3%. In term of years of adoption, none of the respondent adopts the software more than 10 years. And the five highest reported problems as follows: inadequate skills/experience; getting employee trained; poor vendor support; the underestimated effort required for system implementation; and poor performance of software

Up-to-date, regardless of the high popularity of the accounting software packages adoption, very few in the academic literature have developed curiosity towards the usage of this software to support the small business operations. This paper thus attempts to explore the usage of the accounting software packages for small business application from the perspectives of the end user. The ultimate objective of this paper is to investigate the data entry task, in which constitutes a higher proportion of usage of the accounting software packages targeted for small business. The quality of data entry undeniably is fundamental towards derivation of better and useful information for business decision-making. Within the Theory of Technology-Task Fit (TTF), this paper raises

an argument that the embedded design of software navigation for data entry tasks will affect the quality of the task performance. Further, this will contribute to the quality of user experience and will affect their perception towards the quality of the software. This research proposes an innovative way of embedded design of software navigation for the data entry has to be one of the importance attributes for small business decision-making adoptions of the accounting software packages. And for the entrepreneurs of the accounting software packages, an innovative way of designing the software navigation for data entry can be an important determinant to differentiate their products quality with the competitors. The entrepreneurs or the software creators of the accounting software packages thus should not neglect the innovation part of designing the software navigation for the data entry tasks.

This paper is organized as follows. Section II focuses on the review of the Task Technology Fit (TTF) theory as a theoretical basis to support the research argument. In addition, it also includes the literature overview on the software technology and the nature of the business as well as the data entry task in relation to the users' performance and implications. Further, Section III explains the research methodology and analysis of the sample software. Section IV discusses the finding and concludes the study.

LITERATURE REVIEW

The Task-Technology Fit (TTF) Theory

Goodhue (1995) proposed the Task-Technology Fit (TTF) model as a mechanism of user evaluations on the information system success. TTF is "the extent that technology functionality matches task requirements and individual abilities" (Goodhue, 1995:1829). The basis of the TTF model is that the individual user will give higher evaluation on the utilized information system (IS) if the technological or system characteristics fits or matches the nature of the carried task. In addition, the model argued that the user capabilities and skills will also affect the IS evaluation performance. Four hypotheses were empirically tested in the study. The findings support the propositions that user evaluations of TTF are affected by the characteristics of the technology, the characteristics of the task as well as the individual's skills and abilities. Within the technological or system characteristics, Goodhue (1995) proposed that the integrated, common systems of IS, in which reducing the user's confusion, increasing the user understandability, locatability, accessibility and compatibility will lead the user to give higher evaluation performance. Besides, the user will also give higher evaluation performance with easy access of workstation penetration, high level of assistance ratio and the availability of the decentralized unit of assistance to help users in using the system. The task characteristics range from the variety and difficulty of the task, the interdependence of the task and "hands-on" task. Goodhue (1995) argued that, the user who are involved in variety and difficult tasks, and the tasks are interdependent with other organizational units, and to complete the tasks, the user is required to use certain technical skills or techniques (i.e. the use if third or fourth generation language) to interact with the system will lead the user to give lower evaluation performance. User evaluations of TTF also found to have affected by the interaction between the task, the technology and the individual characteristics.

Goodhue and Thompson (1995:213) have extended TTF view within the argument that "for an information technology to have a positive impact on individual performance, the technology must be utilized, and the technology must be good fit with the tasks it supports". The model called the Technology-to-Performance Chain (TPC) is derived the proposed TTF earlier in Goodhue (1995) as the predictor of performance, with the inclusion of user attitudes and beliefs as the predictor of utilization. Goodhue and Thompson (1995) based on the existing theories on users' attitude and behavior (see Goodhue, 1995 and Goodhue and Thompson, 1995 for details) proposed that the occurrence of the mandatory and non-mandatory utilization of the system affect the user's belief and attitudes, and further will affect the user's performance impact. Performance impact is related to the issues of achievement of tasks with a degree of changes in term of variables such as task efficiency and effectiveness, and quality gain. In other words, the significant improvement in the task productivity signifies higher performance impact on using the system, and vice versa. The findings reveal that the technological proposed characteristics of the technology, although not all characteristics do affect TTF. And for the tasks and user interactions, the study found differences contributed by the different job levels (i.e. compatibility and ease of getting authorization). Overall, the finding moderately supports that the task and the technology does affect users in evaluating TTF. However, the study failed to demonstrate that TTF as a predictor of utilization. They argued few possibilities to explain the failure. The explanation include the exclusion of the user's duration and frequency usage of the system, the domination of other influences on the user's attitudes and behavior such as social norms, habit etc as compared to TTF in utilizing the technology, and the limitation of the research design in which the variation of IS characteristics used must be taken into consideration. The findings further reveal that the use of TTF and utilization together appears to perform better in predicting performance impact, rather than using the utilization alone.

Software Technology, Data Entry Task and Users

"Software-nothing but pure knowledge in codified form-largely drives and enables today's economy" (Hoch et al, 1996:6). Software is a production based on the continuous innovation, creativity and efforts either from the entrepreneurs or the software creators. Quinn et al (1996) argues that software is an essential component of all aspects of innovations in business. They propose the significance role of software that ranges from the basic and applied research to the development area, manufacturing, organizational learning and other critical areas that are significance towards the promotion of innovation in business. A high quality software requires creators to have a specialized domain of knowledge, wide and diverse technical skills and high-level of user-sensitivity. Carmel and Sawyer (1998) have observed differences between the packaged software firms and the custom IS development firms. Packaged software firms design and produce software products that are targeted for mass market. The custom IS development firms build custom IS systems based on-ongoing contract or on consultation basis. Thus, the IS custom firm is much more people and process oriented, whereas the packaged software firm is more product and market oriented. Based on the industry, development, team, and cultural milieu as dimensions for analysis, Carmel and Sawyer (1998) concluded few distinct attributes of the packaged software firms in contrast to the custom IS firms on their study. Due to the purpose of mass market, the packaged software business is based on profit and market share as the indicator for success, while the custom IS business uses user satisfaction and acceptance of the system as success indicator. For the packaged software firms, the development structure is based on line positions, the design and development process is integrated, and coordination play roles to control or manage the design. User is normally not involved in the development of the software. The packaged software firm also tends to be highly entrepreneurial and individualistic. Because of the business culture that emphasize on highly entrepreneurial and individualistic, the packaged software team tends to be self-managed, motivated and willing to work long hours. The team also may have multiple involvements in the software development life cycle and sharing vision for their product.

The packaged software is attractive to small business because they are affordable, and easy to install and use due to the less requirement of technical expertise (Cragg and King, 1993). The characteristics of the accounting software packages within the category of the low end, the mid-range and the high-end packages proposed by Tavakolian (1995) has changed and less applicable in today's market due to the fast innovation in the software technology. For instance the mid-range accounting system has been observed to slowly moving towards the Web adaptation for e-commerce support (Davis, 2000). Dhaliwal and Konsyuki (1980) prescribed technical considerations to ensure the integrity of the input data in the computerized accounting systems. The emphasis to ensure the data integrity must be given at the initial stage of the activity session when operators interact with the system. Specifically the activities such as converting and transmitting data from source documents to the production of turnaround documents and other form of analysis for further usage in business transactions. Input validations from the software embedded modules or techniques as part of data integrity control mechanisms can range from the validity tests, completeness tests, logical tests, limit tests, self checking digits and control totals (refer to Dhaliwal and Konsyuki, 1980 for details). One interesting aspect highlighted by Dhaliwal and Konsyuki (1980) is the form of job designation that contradicts with the nature of the software (i.e. the authorization applies to only one role, but job made two roles). In addition, the data entry activities can be the typical form of errors that affect the integrity of data.

Data entry task is fundamental towards ensuring the quality of data in the system. Jinks et al (2003) for instance presents their analysis on the data entry task in the field of healthcare. Specifically the activities of data entry task of using Teleform. Teleform is a computer-assisted data entry system to support the clerks' data entry job. The experience and skills of the clerks as users are proven to be significant in the error reduction of the data entry. In addition, the characteristic of the technology such as the user-friendliness of the Teleform also contributes to the data entry task efficiency. Heavily involved in massive data entry activities can also led to physical and psychological problems. The visual fatigue, musculoskeletal disorders such as low back pain, carpal tunnel syndrome (CTS) and job stress are the common problems experienced by the computer users including the data entry clerk/operator/user. Balci and Aghazadeh (2004) present their analysis that frequent work-rest schedule is significant towards minimizing the effects on discomfort, performance, and muscular load levels. The embedded software navigation design thus can play significant roles in reducing possible health problems for the user that involves in massive data entry task activities.

RESEARCH METHODOLOGY AND ANALYSIS

Two accounting software packages have been acquired from the local market. For the purpose of this study, the analysis and discussion will refer the Software 1 as S1 and the Software 2 as S2. The price of these software ranges from MYR1500.00 to MYR2500.00 and both software are widely available in the local market. Generally, the embedded modules application (i.e. AR, AP, GL, Invoicing etc) in both software are targeted for

the small business financial or accounting operations. For the purpose of this study, two partial extractions of the software design for data entry presented in the form of column and row (Table 1 for S1, and Table 4 for S2). This is one of the typical forms of input design for the data entry. The method will enable the analysis of the embedded navigation development approach for S1 and S2 towards the task completion of the data entry. The data entry task is partially based on the complete activities of *the task scenario of new sales order for an item/product preparation for new customer* using the software. The detail analysis and explanation only reflect one routine of navigation for data entry with the input screen. In reality, users' routines of navigation for data entry with the input screen are varied and difficult to quantify. The use of one routine is sufficient for the purpose of this research study that is to raise an argument that the embedded design of navigation for data entry task contributes to the quality of the task performance. As proposed by the TTF theory, the degree of fit is determined by the technology characteristics and the task characteristics. Thus the embedded design of navigation of S1 and S2 as presented through the extraction of partial tasks of data entry will provide good observation towards the effect of the navigation design techniques as one characteristic of the software technology that have direct contribution to the quality of task performance.

Analysis of the Software 1 (S1)

Table 1: Partial Extraction of Data Entry Task of S1

COL1 (Quantity)	COL2 (Product Nc)	COL3 (Descriptior)	COL4 (Acc Nc.)	COL5 (Amount)	COL6 (Job)	COL7 (Tax)

There are seven columns for the data entry task. The observed generic navigation techniques applies to these seven columns include the common Mouse Operation and keystroke such as Tab Key, Shift Tab Key, Escape Key and Control Tab Key (see Table 2). The availability of Mouse Operation helps to improve the users' performance for data entry task. The use of Escape Key for exiting the sales data entry screen however can cause users' frustration because no warning or reminder dialog box to users to save their data entry works before exiting the screen. If the user has accidentally pressed the Escape Key, and the user does not save the current work yet, than the user has to start the task all over again. This undeniably can affect the quality of the task performance.

Table 2: Generic Navigation Techniques Apply to All Columns of S1

Navigation Technique	Role in Data Entry Task
Mouse Operations	Advance cursor to begin data entry
	To move to the previous input box
	To move to the next input box
	To move to the next row
Tab Key	Advance cursor to begin data entry
	To move to the next input box
Shift Tab Key	Advance cursor to begin data entry
	To move to the previous input box
Escape Key	Automatic exit the sales input screen to the main screen with no interaction to ask if users want to save the record or not
Control Tab Key	To go to the main screen

S1 also contains embedded navigation techniques apply to the specific columns (see Table 3). For instance, the use of Spacebar Key to trigger calculator tool for Column 1, Column 4, Column 5 and Column 6. The Spacebar Key to trigger utility such as the calculator tool is not a typical representation of navigation key technique for the accounting software packages. The user thus is expecting to know in advance through manual or online help that this utility available to be used. The used of Enter Key is also not consistent in the navigation design. In Column 3 for instance, the user cannot use the Enter Key to move to the next input box as other columns. The inconsistent use of Arrow Up Key and Arrow Down Key is also apparent in the S1 navigation design. The use of the Arrow Down Key in Column 2 for instance will navigate to the next row of the same column for data entry and not to the next input box as applies to rest of the columns. In Column 3, the Arrow Up Key and Arrow Down Key are not available as navigation techniques.

Table 3: Specific Navigation Techniques Apply to Specific Columns of S1

Columns	Navigation Technique	Role in Data Entry Task
Column 1 (Quantity) Function: To input the quantity that has been ordered by the clients	1. Enter Key	Advance cursor to begin data entry To move to the next row
	2. Arrow Up Key	To move to the previous input box Advance cursor to begin data entry
	3. Arrow Down Key	To move to the next row Advance cursor to begin data entry
	4. Space Bar Key	To trigger calculator tool
	Navigation Technique	**Role in Data Entry Task**
Column 2 (Product/Item No) Function: To select/input the product/item number	1. Mouse Operations	To trigger the item number list for selection To click on the command button from the list box to proceed
	2. Enter Key	To trigger the item number list for selection To move to the next input box
	3. Arrow Up Key	To move to the previous input box Advance cursor to begin data entry
	4. Arrow Down Key	To move to the next row in the same column Advance cursor to begin data entry
Column 3 (Description) Function: To input the description of the product	**Navigation Technique**	**Role in Data Entry Task**
	1. Enter Key	Advance cursor to begin data entry To move to the next line for data entry
	Navigation Technique	**Role in Data Entry Task**
Column 4 (Price) Function: To input the price of the product	1. Enter Key	To move to the next row
	2. Arrow Up Key	To move to the previous input box
	3. Arrow Down Key	To move to the next input box
	4. Space Bar Key	To trigger calculator tool
	Navigation Technique	**Role in Data Entry Task**
Column 5(Discount Rate) Function: To input the discount rate if applies	1. Enter Key	To move to the next row
	2. Arrow Up Key	To move to the previous input box
	3. Arrow Down Key	To move to the next input box
	4. Space Bar Key	To trigger calculator tool
	Navigation Technique	**Role in Data Entry**
Column 6(Total) Function: Auto calculates the total based on the price, unit and discount rate if applies. Users can change the total with no warning message if errors occur.	1. Enter Key	To move to the next row
	2. Arrow Up Key	To move to the previous input box
	3. Arrow Down Key	To move to the next input box
	4. Space Bar Key	To trigger calculator tool
	Navigation Technique	**Role in Data Entry**
Column 7(Job) Function: To input the job type that involve	1. Enter Key	To move to the next row
	2. Tab Key	To trigger the item number list for selection
	3. Arrow Up Key	To move to the previous input box
	4. Arrow Down Key	To move to the next input box
	Navigation Technique	**Role in Data Entry**
Column 8(Tax) Function: To input the job type that involve	1. Enter Key	To move to the next row
	2. Arrow Up Key	To move to the previous input box
	3. Arrow Down Key	To move to the next input box
	4. Space Bar Key	To trigger calculator tool

Analysis of the Software 2 (S2)

Table 4: Partial Extraction of Data Entry Task of S2

COL1 (Item/Product	COL2 (Quantity)	COL3 (B/O)	COL4 (Unit)	COL5 (Description)	COL6 (Price)	COL7 (Amount)	COL8 (Tax)	COL9 (ACCOUNT)

There are nine columns for the data entry task. The observed generic navigation techniques apply to these columns are the Mouse Operations and the common keystroke such as Tab Key, Shift Tab Key, Control Tab Key, Arrow Up Key and Arrow Down Key (see Table 5). The availability of Mouse Operations helps to improve the users' performance for the data entry task. S2 utilize the Arrow Up Key and Arrow Down Key consistently to signify navigation to the upper and lower line for data entry. S2 improvised the quality of user experience for data entry task by maximizing the number of common navigation keys in comparison to the S1.

Table 5: Generic Navigation Techniques Apply to All Columns of S2

Navigation Technique	Role in Data Entry Task
Mouse Operations	Advance cursor to begin data entry
	To move to the previous input box
	To move to the next input box
	To move to the next row
Tab Key	Advance cursor to begin data entry
	To move to the next input box
Shift Tab Key	Advance cursor to begin data entry
	To move to the previous input box
Control Tab Key	Advance cursor to begin data entry
	To move to the previous input box
Arrow Up Key	To move to the next line (upper) within the same column
	Advance cursor to begin data entry
Arrow Down Key	To move to the next line (lower) within the same column
	Advance cursor to begin data entry

Because of the availability of the generic keys, only a small number of columns embedded with specific navigation techniques. All of these techniques (i.e. Column 1, Column 4, Column 8 and Column 9) are consistently design for specific navigation. Besides, the visible cues for mouse clicking provide better assistance for the users.

Table 6: Specific Navigation Techniques Apply to Specific Columns of S2

	Navigation Technique	Role in Data Entry Task
Column 1 (Item/Product Number) Function: To input the item/product number that has been ordered by the clients	1. Mouse Operations	To trigger the item/product number list for selection. Icon is visible for mouse clicking. To click on the command button from the list box to proceed.
	2. Enter Key	To trigger the item/product number list for selection. To move to the next input box
Column 2 (Quantity) Function: To input the item/product number that has been ordered by the clients	None	
Column 3 (Back Order) Function: To input the back order quantity if applies	None	

	Navigation Technique	Role in Data Entry Task
Column 4 (Category of Unit)) Function: To input the category of unit applies to the product	1. Mouse Operations	To trigger the unit category list for selection. Icon is visible for mouse clicking. To click on the command button from the list box to proceed.
	2. Enter Key	To trigger the unit category list for selection. To move to the next input box
Column 5 (Description) Function: To input the product description	None	
Column 6 (Price) Function: To input the product price	None	
Column 7 (Total Amount) Function: Auto calculates the total based on the price and unit. Users can change the total amount and column price is auto adjusted.	None	
	Navigation Technique	**Role in Data Entry Task**
Column 8 (Tax) Function: To input the tax category	1. Mouse Operations	To trigger the tax list for selection. Icon is visible for mouse clicking. To click on the command button from the list box to proceed.
	2. Enter Key	To trigger the tax list for selection. To move to the next input box
	Navigation Technique	**Role in Data Entry Task**
Column 9 (Account) Function: To input the account category	3. Mouse Operations	To trigger the account list for selection. Icon is visible for mouse clicking. To click on the command button from the list box to proceed.
	4. Enter Key	To trigger the account list for selection. To move to the next input box

DISCUSSION AND CONCLUSION

In conceptualizing the TTF on the specific domain of the accounting software application, the data entry tasks and the characteristics of the embedded design of software navigation will determine the degree of fit. The degree of fit determines the task performance of the users in completing the task using the software technology. Within the context of this study, the data entry task is an independent task and routine in nature. The speed of data entry, in addition to the quality task of the data entry performed by the users will determine the quality data that is being fed into the system. As demonstrated by few researchers, users' experience, attitudes and skills contributes to the quality of the data entry task. Thus ideally, the embedded design of software navigation must support the nature of the data entry task. The embedded design of navigation of the accounting software packages thus must contain ability to enhance the speed quality of the data entry, in addition to the support mechanisms that can lead to the achievement of zero data entry errors.

As presented in the previous section, there are some apparent differences between S1 and S2 in the approach design of the software navigation. S2 approach is more systematic, thus the embedded navigation techniques are consistent and predictable to the user throughout the process of completing the data entry task. In addition, the visible cues and the appropriate selection of keystroke for navigation will enhance the quality of the user experience. S1, with the inconsistent navigation design will impose difficulty on users to complete the data entry task. Within this simple analysis, users' performance speed will be negatively affected due to this inconsistency. Lacking of the visible cues to signify the correct navigation technique (i.e. visible icon for mouse clicking) in addition to the availability of Escape Key to automatically exit from the current input screen without warning can also affect the user quality experience in using the system. Further, if users accidentally changed the data of the total amount (Column 6), the new changes will not affect the set price. Here, the calculation error obviously occurs. In the other hand, if any changes in S2 pertaining to the total amount (Column 7) either accidentally or intentionally performed by the users, the price is auto adjusted to reflect the current change of the total amount. As demonstrated by the analysis, one can easily stipulate that S2 navigation design is much more sensitive and

fully reflects on the technological requirement of the data entry for optimum level of performance as compared to S1.

This research has been able to demonstrate how innovation of the creator can play significant role towards the quality of the task performance of the user. In the production of the accounting software, the entrepreneur or the creator must not ignore the innovative part of designing the navigation techniques in order to ensure the produced software can be efficiently adopted by the end users. Based on the application of the TTF Theory, this study has highlighted the importance of the innovative development of the navigation technique on the software to be treated as one of the differentiator qualities of the software in making comparison to the other competitors in the industry. For the potential adopters (i.e. small business owners/managers) of the accounting software packages, the innovative navigation design of the software shall be one of the attributes of the decision-making criteria for adoption if the nature of the tasks is dealing with massive and frequent data entry.

Attitudinal Factors Contributing to Organizational Commitment among Employees in an East Malaysian City

Chong Siaw Fung
Actionpoint Professional Services Sdn. Bhd.
P O Box 16245
88869 Kota Kinabalu, Sabah
E-mail: csfung@pc.jaring.my

ABSTRACT

Organizational commitment is often associated with job effectiveness, level of satisfaction, and the employees' intention to quit or stay with their organizations. Individuals with higher level of commitment to the organization are more likely to put in efforts to add value to the organization. They would be more willing to contribute their ideas, co-operate with their superiors, follow instructions and directives from the management, and engage themselves in activities that they perceived as beneficial to the organization as a whole. As such, employees with strong organizational commitment are definitely desirable, and subjects related to factors contributing to organizational commitment would inevitably be of interest to employers and managers. In this study, it is hypothesized that employees' self-efficacy, job involvement, and perceived organizational support would be among the factors contributing to organizational commitment. Standardized scales developed to measure these factors were adopted to collect data from a total of 95 employees from six organizations in various industries in Kota Kinabalu. It is found that perceived organizational support contributed most significantly to organizational commitment. The contributions of self-efficacy and job involvement are also found to be significant, although far weaker than that of perceived organizational support.

INTRODUCTION

The Hawthorne studies taught us lessons about how the workers' attitudes and social behaviors may affect their performance and productivity. Over the years, researchers had studied various attitudinal factors that may have influenced worker productivity. Organizational commitment is one of those factors frequently examined. One significant attempt to operationalize the measure of the factor was done by Mowday, Steers, and Porter (1979). They defined organizational commitment as "…the relative strength of an individual's identification with and involvement in a particular organization" (p.226). They contended that it can be characterized by at least three related factors:

- A strong belief in and acceptance of the organization's goals and values;
- A willingness to exert considerable effort on behalf of the organization; and
- A strong desire to maintain membership in the organization.

A highly committed employee would accept the goals and values of the organization, be willing and motivated to exert high levels of energy on behalf of the organization, and would exhibit desirable employee behaviors as a part of the organization. Such characteristics in an employee would indeed make him or her valuable to any organization.

Effects of Organizational Commitment

There are some valuable research findings pertaining to the influence of organizational commitment on worker attitudes and performance. Organizational commitment was found to be associated positively with job satisfaction of employees (Glisson & Durick, 1988; Mowday et al, 1979; Porter, Crampon, & Smith, 1974; Porter, Steers, Mowday, & Boulian, 1974). In a more specific study, it was found that where there is no conflict between organizational loyalty and professional standards among a sample of accounting professionals, organizational commitment correlates positively with job satisfaction (Norris & Niebuhr, 1983).

Organizational commitment has been found to have direct and indirect effects on work performance and behaviors. Mowday, Steers, and Porter (1979) discovered positive correlation between organizational commitment and supervisor-rated work performance. In another study, organizational commitment was observed to mediate relationship of leadership behavior with job satisfaction and performance (Yousef, 2000). In addition, organizational commitment was also found to be associated with employees' attendance, turnover,

and intention to stay with or leave an organization (Mowday et al, 1979; Porter, Crampon, & Smith, 1976; Porter, Steers, Mowday, & Boulian, 1974; Steers, 1977; Stevens, Beyer, & Trice, 1978).

Predictors of Organizational Commitment

It is quite widely accepted that individual characteristics of employees are likely predictors of organizational commitment. For instance, age, gender, education, and employment tenure of employees are among the characteristics that are quite effective in predicting organizational commitment (Batesman & Strasser, 1984; Koch & Steers, 1978; Morris & Sherman, 1981; Steers, 1977; Stevens, Beyer, & Trice, 1978). However, it appears that the effects of these individual characteristics may be indirect, often mediated by other attitudinal factors (Mottaz, 1988).

In the process of ascertaining the determinants of organizational commitment, Mottaz (1988) concluded that intrinsic rewards – personal-related factors that are considered rewarding by the employees – are more powerful determinants of organizational commitment than social and organizational rewards. This pattern appeared to be consistent across different occupational groups of sample in the study. This reflects that employees' attitudinal factors have significant impact on the level of their organizational commitment.

One such factor that may affect employees' organizational commitment is their level of self-efficacy. This refers to the general feelings they have on their capability to cope with the challenges they face. Employees with higher levels of self-efficacy would be more confident with their competence at work, and more likely to exercise initiatives to add value to their organizations. Morris and Sherman (1981) found that employees with greater sense of competence tend to have higher level of organizational commitment.

Employees' job involvement appears to be associated with organizational commitment. Stevens, Beyer, and Trice (1978) reported the employees' ego involvement with their jobs have significant positive correlation with their levels of organizational commitment. In another study, organizational commitment was observed to have positive correlation with job involvement (Mowday et al., 1979).

Apart from the above factors, organization-related factors such as leadership behaviors (Batesman & Strasser, 1984; Morris & Sherman, 1981; Yousef, 2000) and the extent to which the organization is seen as dependable (Buchanan, 1974; Hrebiniak, 1974; Steers, 1977) were found to be significant predictors of organizational commitment. Employees' perceived organizational support appeared to have contributed to stronger feelings of affiliation and loyalty to the organization (Eisengerger, Fasolo, & Davis-LaMastro, 1990). Perceived organizational support of employees was found to be positively correlated with the various domains – affective, continuance, and normative – of commitment (LaMastro, 2003) and with organizational commitment specifically (Shore & Tetrick, 1991).

RATIONALE OF THE STUDY

Since the 1980s, the state government of Sabah has concerted efforts to take on the challenges brought about by a new economy. These challenges are well described by Richard and Ti (1989):

> As a developing economy with a dominant primary commodity export base, Sabah is highly sensitive to changes in the global environment. …It is becoming increasingly apparent that the industrial world has reached a plateau of growth thereby changing the market for primary products. …Sabah needs to develop a more diversified value-added economy to be better able to compete in today's global environment and thereby ensure long-term growth. (p.3)

As a response to these challenges, human resource is among one of the ingredients for growth to be put in place to enhance the state's competitiveness according to the Sabah Action Blueprint (Institute for Development Studies, 1987).

As more efforts of industrializing the state economy are in progress, the demand for human resources would definitely increase (Chua, 1999). On a statewide scale, it was reported that as at September 2002, the total number of employed persons in Sabah was approximately 1.062 million (Institute for Development Studies, 2003), comparing to 332,345 in 1980 (Richard & Ti, 1989).

In the management and development of human resource, employee attitudes and performance are major concerns of employers everywhere. As human resource management becomes one of Sabah's main ingredients for growth, there are needs to determine factors that may contribute positively to employee performance and

productivity. This study attempts to determine the factors contributing to organizational commitment, which is one factor likely to affect employee work performance – directly or indirectly (Glisson & Durick, 1988; Mowday et al, 1979; Porter et al, 1974; Porter et al, 1974; Steers, 1977; Stevens et al, 1978).

Although employees' individual characteristics may have contributed to their organizational commitment to a certain extent, such effects may have been indirect and perhaps mediated by other attitudinal factors. When advance in age, with limited educational attainment, and after working with an organization for a considerable long period of time, the employee's level of organizational commitment – especially in the continuance domain – would inevitably be higher due to the lack of alternative career options. While acknowledging that these factors could be helpful as predictors of organizational commitment, Mottaz (1988) proposed that theoretical consideration of the effects of attitudinal factors would be more relevant to further understand and explain what determines and contributes to organizational commitment.

The rationale of this study is that attitudinal factors of employees would contribute significantly to organizational commitment. The confirmation of such effects would help employers understand and explain how the level of organizational commitment of their employees is affected in order to derive human resource management strategies that would improve employee attitudes and organizational commitment, and ultimately their productivity at work.

RESEARCH HYPOTHESIS

The purpose of this study is to determine the degree to which employee attitudes contribute to their organizational commitment. Specifically, the attitudinal factors considered are self-efficacy, job involvement, and perceived organizational support. The hypothesis of this study is that

H1: Self-efficacy, job involvement, and perceived organizational support of employees will have significant effect on their levels of organizational commitment.

PROCEDURES

This study is conducted among six organizations in Kota Kinabalu from various industries – education, information and communication technology, property development, accounting and management services, and public service. These organizations employ in total about 200 employees of various ethnic backgrounds who are mostly Sabahans or permanent residents of the state of Sabah.

A survey is conducted among the employees of these organizations through their management. Survey instrument is distributed to and collected from the employees by their management. A total of about 150 forms were distributed to the operatives of the organizations – executives, officers, and those who made up the main operating core of the organizations. They were given about one week to complete the form and submit it back to their management. A total of 96 forms were collected back, making a response rate of about 64.0%. Out of the 96 forms collected, one form was only half completed and was discarded from further consideration. Thus, the number of responses considered for statistical analysis is only 95.

Subjects

The subjects of this study are employees who are among the operating workforce of six organizations in Kota Kinabalu. Responses from a total of 95 subjects were analyzed. The subjects are made up of various ethnic backgrounds – Kadazan and Dusun (22.1%), other native groups of Sabah (19.8%), and Chinese (58.1%). In terms of job tenure, 62% of the subjects had worked with their present organization for one to three years and four subjects had worked with their present organizations for more than 10 years.

SURVEY INSTRUMENT

The survey instrument for this study consists of scales to measure self-efficacy, job involvement, perceived organizational support, organizational commitment, and other factors included for pilot test of another study. It has a total of 116 Likert-scaled items on a 7-point scale (from "Strongly disagree" to "Strongly agree"). The scales to measure self-efficacy, job involvement, perceived organizational support, and organizational commitment are adopted from previous studies, and had demonstrated fairly high degree of validity and reliability.

Self-Efficacy

Self-efficacy is measured by using the 17 items in the General Self-Efficacy Scale developed by Sherer, Maddux, Mercandante, Prentice-Dunn, Jacobs, and Rogers (1982). Cronbach's alpha coefficient for the scale was determined to be .86 when administered among 376 students in an introductory psychology course and demonstrated criterion validity when tested with 150 inpatients in a medical institution (Sherer et al., 1982).

Job Involvement

Job involvement is measured by using the 20 items developed by Lodhal and Kejner (1965). They defined job involvement as "…the degree to which a person's work performance affects his self-esteem" (Lodhal & Kejner, 1965, p.25), and elaborated it as

> …the internalization of values about the goodness of work or the importance of work in the worth of the person, and perhaps it thus measures the ease with which the person can be further socialized by an organization. (p.24)

According to them, job involvement is acknowledged to be a multidimensional attitude, and thus it can be scaled with adequate, but not high reliability. The 20 items for the Job Involvement scale was developed and tested through three rounds – involving 137 nurses, 70 engineers, and 46 graduate students respectively. The split-half reliability of the 20-item scale was adequate but not extremely high – ranging from .56 (for nurses) to .80 (for graduate students). Corrected by means of the Spearman-Brown formula, the split-half reliability ranges from .72 (for nurses) to .89 (for graduate students). There were sufficient evidence to establish the validity of the scale in terms of discrimination and congruence.

Perceived Organizational Support.

Perceived organizational support is the employees' perception of their organization's care and concern for their well being in general. Eisenberger, Huntington, Hutchison, and Sowa (1986) postulated that there will be agreement in the degree of support from the organization expected by employees in a wide variety of situations. Based on this hypothesis, they developed a 36-item instrument to measure perceived organizational support. These items were tested on 361 employees from nine organizations of various industries – manufacturing, finance, telecommunication, retail, legal service, education, and postal service. Factorial validity was determined by confirmatory factor analysis. The Cronbach's alpha value was found to be .97, and item-total correlations ranges from .42 to .83, with mean and median of .67 and .66 respectively. These items were often used for studies on perceived organizational support, and its factorial validity and reliability remain consistently high. In the second study reported in the same paper, Eisenberger and colleagues (1986) used 16 items from the original 36 items, yielding Cronbach's $\alpha = .93$. For this reason, these 16 items were used in the present study to measure perceived organizational support.

Organizational Commitment. The 15 items developed by Mowday, Steers, and Porter (1979) was used to measure organizational commitment. These items were tested on 2,563 employees from nine different work organizations – hospital, public agency, university, telecommunication company, etc. The responses to the questionnaire were found to be highly consistent (α ranges from .82 to .93 with a median of .90). Favorable evidence was also found for test-retest reliability for two samples over two-, three-, and four-months period ($r = .53, .63, .75$ for psychiatric technicians, and $r = .72, .62$ for retail management trainees). Evidence of validity – convergent, discrimination, and predictive – was also adequately obtained.

RESULTS

Out of about 150 survey forms distributed, 96 forms were collected back. One form was discarded because it was incomplete. The total number of responses submitted for data analysis is 95. The data was entered and sum of scores for each scale – self-efficacy, job involvement, perceived organizational support, and organizational committed – was computed. The correlation between these factors was then determined (Table 1).

Table 1: Correlation Matrix for Attitudinal Factors affecting Organizational Commitment

	Self-Efficacy	Job Involvement	Perceived Organizational Support	Organizational Commitment
Self-Efficacy	1.000	.503*	.367*	.582*
Job Involvement	.503*	1.000	.517*	.619*
Perceived Organizational Support	.367*	.517*	1.000	.724*
Organizational Commitment	.582*	.619*	.724*	1.000

* $p < .01$ (2-tailed)

It is observed that all the factors are significantly correlated with one another ($p < .01$). Specifically, self-efficacy, job involvement, and perceived organizational support have significant correlations with organizational commitment (Pearson r = .582, .619, and .724 respectively). In order to examine the extent to which these factors contribute to the variance in organizational commitment, regression analysis is performed.

Based on the correlation analysis, linear regression is performed with organizational commitment as the dependent variable. Having the highest correlation with organizational commitment, perceived organizational support is entered first, followed by job involvement, and finally self-efficacy. The results yielded are displayed in Table 2.

Table 2 : Attitudinal Factors Contributing to Organizational Commitment

Predictors	R	R^2	ΔR^2	Sig. F Change
Perceived Organizational Support	.724	.524	.524	.000
Job Involvement	.841	.708	.028	.008
Self-Efficacy	.824	.679	.155	.000

Dependent Variable: Organizational Commitment

All the predictors contribute significantly to the variance in organizational commitment. Perceived organizational support contributes the highest variance (ΔR^2 = .524, p<.01) as expected. However, despite of having higher correlation with organizational commitment, job involvement (ΔR^2 = .028, p<.01) contributes less than self-efficacy (ΔR^2 = .155, p<.01) to the variance of organizational commitment.

DISCUSSION

Although employee characteristics such as age and job tenure could be good predictors of organizational commitment, this study focused on attitudinal factors of employees. It is the rationale of this study that the understanding of such effects would help employers and managers to predict, manage, and control the behaviors of their employees more effectively, especially in the efforts of promoting organizational commitment.

Results from the data analysis yielded significant evidence that perceived organizational support, job involvement, and self-efficacy of the subjects would contribute to the variance in their organizational commitment. Furthermore, perceived organizational support appeared to be the more dominant factor among the three in consideration. This suggests that employees who perceive their organizations as supportive would be more likely to be committed to the organization. This finding is in agreement with several previous studies, which had indicated that, perceived organizational support is positively associated with various aspects of organizational commitment (Eisengerger, Fasolo, & Davis-LaMastro, 1990; LaMastro, 2003; Shore & Tetrick, 1991).

The significance of perceived organizational support as a predictor of organizational commitment of employees (ΔR^2 = .524, p<.01) deserves serious attention from employers and managers. This would imply that organizations wanting to promote organizational commitment should place employees' welfare among the top agenda pertaining to human resource management and development strategies. Some strategies to improve perceived organizational support among employees include involvement of employees in policy and operational planning, proper assessment and understanding of employees' needs, design and formulation of policies based on employees' feedback, and so on.

It is found that self-efficacy of employees contribute more significantly to their organizational commitment (ΔR^2 = .155, p<.01) than job involvement (ΔR^2 = .028, p<.01). It seems that those who are highly involvement in their job are less likely to be committed to their organizations comparing to those with high self-efficacy.

They may love their jobs, but that may not necessarily mean that they are loyal and devoted to their organizations. On the other hand, employees with higher level of self-efficacy are likely to be more confident with their job competence. Thus, they may be less vulnerable to influences that may affect their organizational commitment negatively. This seemed to indicate that – to promote organizational commitment – employers and managers should focus more efforts in enhancing self-efficacy of employees.

In order to enhance self-efficacy of employees, employers and managers have to understand how self-efficacy is developed. In their study, Bandura, Adams, and Beyer (1977) discovered that self-efficacy may change over the process of a behavioral change, such as through participation in completing a new task (participative learning), or by observing someone successfully complete the new task (modeled behavior), such as in simulations and on-the-job training. Similarly, it was also observed in several other studies that training experiences would significantly affect self-efficacy (Gist, 1989; Tannenbaum, Mathieu, Salas, & Cannon-Bowers, 1991). Therefore, employers and managers should develop systematic strategies in training and developing their employees, provide them with opportunities to try out newly acquired skills, and autonomy in solving work-related problems to help them develop self-efficacy.

Employers and managers should also constantly review job designs of employees. Operational routines may cause boredom at work and subsequently negatively affect job involvement of employees. Thus, job tasks of employees – scope and design – should be reviewed, enriched, and enlarged over time to create job challenges. Together with the other strategies to reinforce perceived organizational support and self-efficacy, job involvement would be enhanced. Collectively, these would contribute towards organizational commitment.

CONCLUSION

Although employee characteristics such as age and job tenure may be good predictors of organizational commitment, understanding of how attitudinal factors of employees affect their organizational commitment is important for more effective management and control of employee behaviors. The results in this study supported the hypothesis that self-efficacy, job involvement, and perceived organizational support of the subjects significantly contribute to their organizational commitment. Perceived organizational support appeared to contribute most ($\Delta R^2 = .524$, p<.01) to the variance in their organizational commitment, followed by self-efficacy ($\Delta R^2 = .155$, p<.01), and then job involvement ($\Delta R^2 = .028$, p<.01).

ABSTRACT

Globalisation- a wonderful way of living, doing business and working-along with information technology tend to bring paradigm shifts in human resource management and thereby a fundamental change in industrial relations. The paradigm shifts in human resource management include organization structure based on empowered teams, downsizing, de-layering, team design and analysis in place of job design and analysis, employee referrals and outsourcing in place of lengthy and detailed selection process, considering much of candidates' soft skills viz., attitude, aptitude and emotional intelligence rather than hard skills viz., technical skills, knowledge and abilities, on-line training and development in place of on-the- job and class room training and development , development–oriented performance appraisal and performance-based individual compensation package in place of designation-based uniform compensation package. Thus, these shifts are towards team/synergy based in case of employee contributions to the organization and towards individual/low-cost based in case of organization's contributions to employees.

Industrial relations generally denote the relationship of employees, employer, employees' associations, employers' associations and the State. Industrial relations deal employees in a collective sense. But the paradigm shifts in human resource management have set a stage to bring fundamental change in the concept of industrial relations i.e., shift from collective relationship of employees with the employer to individual relationship of each employee with the employer. In fact this is already set-in in information technology industry. Consequently, the role of other institutions of industrial relations viz., employees' associations, employers' associations and the State, is getting diminished. Thus globalisation tends to reshape the industrial relations as Individual Employee-Employer Relations. As such, individual bargaining slowly replaces collective bargaining, employee associations become weak, and the State slowly shifts its responsibility to the market forces.

This paper is based on the thesis that business environment determines the organisational and human resource strategies and in turn industrial relations pattern. The regulated business environment leads to formulating controlled and protective organisational strategies that in turn results in welfare-centred human resource strategies. These strategies produce equity-cum- protective based industrial relationswhere, employees' associations, employers' associations and the State protect employees'/employer's rights. On the contrary, deregulated business environment consequent upon globalisation leads to formulating competitive strategies that in turn results in competency building-cum-low-cost centred human resource strategies. These strategies produce individual and performance based industrial relations where market forces decide and defend/offend employee/employer rights.

This paper aims at exploring the shifts in industrial relations pattern consequent upon globalisation. The patterns of industrial relations before and after globalisation are explored, addressed, and compared based on the data and information collected from different types of organizations. Thus, this paper intends to build a model of industrial relations in congruent with globalisation.

INTRODUCTION

The business across the borders of the countries had been carried out since times immemorial. The post World War II period witnessed an unexpected expansion of national companies of mostly capitalistic countries into international or multinational companies. A number of countries initially were capitalistic and the sole objective of business during that stage was profit maximization through cost minimization of all inputs including labour. Then Managements followed commodity approach, machinery concept and factor of production approach to labour. Owners' of businesses in those days exploited the labour by following individual approach to human resource management viz., individual employing techniques, wages based on demand and supply factors and performance of individual employee etc., and maintenance of relations with individual employees, but not with a group of employees. Thus the individualistic approach to HRM in those days resulted in individual based

industrial relations. This approach led to excessive labour exploitation in all sectors in various countries, which resulted in shifting up of economic systems from capitalism to communism consequent upon the great revolutions and /or demand of the masses. Communism in various countries gave fillip to the birth and the growth of trade unions, and other institutions of industrial relations in order to protect the workers from exploitation.

The excessive and undue exploitation of labour was also common in India particularly in tea, coffee and rubber plantations and jute and cotton textile industries until 1920. The cumulative effect of such exploitation led to the formation of first all India trade union in 1920 i.e., All India Trade Union Congress, which inspired the formation of a number of company level trade unions and other all India unions like Indian National Trade Union Congress, Centre for Indian Trade Unions and Hind Mazdoor Sabha (Subbarao, 1999: 511-515). Emergence of these trade unions along with their militant tendency and revolutionary approaches could clog the labour exploitation in organised sector to a greater extent by establishing industrial relations institution like Collective Bargaining, Labour Welfare Officers, Joint Consultative Committees, Standing Orders and Tripartite and Bipartite Bodies. In addition, Government of India started playing its role of custodian of working population by involving itself in the industrial relations process and by enacting labour legislations. These developments changed the individualistic approach to HRM to collective approach, which in turn shifted the industrial relations from individual employee-employer relations to collective relations among employees, employer, trade unions and the Government in India. This had been the experience in various countries adopted mixed economic system or communistic economic system with varied degrees.

India's choice of mixed economic system and subsequent adoption of socialistic pattern of society enabled the trade unions to protect the workers even unduly by regulating the managements with the help of the labour laws in force that resulted in absence of work culture, formation of employee negative mind set, high demands and lower contributions of the employees and the like. This was more prevalent in public sector particularly during 1960s and 1980s. These developments to a considerable extent resulted in negative performance most of the public sector undertakings and limited performance of and low labour productivity in private sector. This situation was prevalent in other countries also particularly in communistic and socialistic countries in varied degree.

At this point of time, most of the economies in the world including the erstwhile communistic counties have chosen capitalistic pattern of society/ market economies in view of the limitations of communism. This global trend along with the huge fiscal deficit and crisis in balance of payments forced the Government of India to globalise its economy in 1991 and create a favourable climate for restoration of capitalistic tendencies or markets economic situations. Papua New Guinea (PNG) is relatively a newly born country, which got its Independence on September 16th 1975. PNG globalised her economy in 1986 along with the major world economies

Globalisation tends to result in exchange of the cultures across the globe, location of manufacturing centres and/or various business processes in and spread of markets to various countries. Thus globalisation led to internationalisation of capital, human resources, markets, material, management and manufacturing posing sever competition to the companies of developing countries from multinational and translational companies not only in their home countries but also in various foreign countries wherever the former operate (Subbarao, 2003:114-121). This multidimensional competition made the companies to align and realign all their strategies, operations and resources including human resources around the customer and customisation approach. Customisation approach to business was in fact, the earliest approach and it is coming back in a different degree (Moffat, 1990: 132-135 and Kotler, 1996: 266-267). This process has its impact on management of various resources including human resources.

Governments in capitalistic economic systems, provide free and deregulated environment to the business to operate and formulate competitive corporate as well as human resource management strategies (Human Resource Management Journal, 1997: 50). Further, globalisation provides free and deregulated environment for the business in all those countries whose economies are opened for the rest of the globe. As such business in such economies centre their strategies on customer, but not on humanness of human resources as they treat all resources equally for the purpose of winning the customer preferences in the short-run and deliciousness in the long-run. The deregulated environment created by the Governments and /or globalisation discourages most of the business regulative institutions or measures including industrial relations institutions, which hampers the freedom of the business to operate competitively. As such the terms and conditions of employment of human resources are mostly determined by the market forces, as is the case with other resources. Therefore, human resource management structure and industrial relations pattern are based on the theme of the corporate strategies that, in turn, are shaped mostly by the country's economic system and/or globalisation. Thus, globalisation along with the capitalistic economic system result in insignificant role for business regulating devices including collective approach to HRM and industrial relations (Sundeep Khanna(1996). Against this thesis, an attempt is

made to find-out the impact of globalisation on human resource management structure and on the industrial relations pattern in the two developing countries viz., India and Papua New Guinea.

OBJECTIVES

The objectives of this paper are:
- To study the impact of globalisation on human resource management structure in Indian public sector and private sector organization in comparison with those of Papua New Guinea,
- To examine the impact of structural changes in human resource management on the industrial relations institutions and pattern in India and Papua New Guinea, and
- To identify the cause and effect relationship among globalisation, human resource management and industrial relations in these two developing countries.

METHODOLOGY

Impact of the globalisation on significant areas of human resource management and industrial relations in selected public and private sector companies in India and Papua New Guinea has been studied. Companies are randomly selected representing both manufacturing and service sectors in India and Papua New Guinea. Both secondary and primary sources of information are resorted to collect necessary information for writing this paper. Structured questionnaires were canvassed electronically to selected companies and trade unions in India and personal interviews were conducted with the present and the former executives, trade union leaders and labour historians in Papua New Guinea in order to collect necessary information. However, limited responses of the respondents and availability of less time at the disposal of the researcher have been the limitations of the study.

IMPACT OF GLOBALISATION ON HUMAN RESOURCE MANAGEMENT

Impact of globalisation on human resource management structure and practices has been studied from the view points of organization structure, job design, human resource planning, employment, performance appraisal, human resource development, career planning, salary and benefits Further, the impact of paradigm shifts in the structure and practice of HRM on industrial relations has been analysed.

Organization Structure

Companies in the past structured their organizations based on functional or departmental and matrix structures and also believed that strategy follows the structure. But Chandler (Chandler, 1962:222) in his research study found that changes in a company's strategy bring about new administrative problems, which in turn, require a new refashioned structure for the new strategy to be implemented successfully. Corey and Star (Corey and Star, 1971) also view that a company's internal organization should be reassessed whenever strategy changes. Organisational structure is a managerial tool in the process of implementation of organizational strategies and in turn achievement of objectives. Thus, companies modify their organizational structures based on the strategy to establish the fit between strategy and the structure.

As stated earlier, organizations used to concentrate on departmental, functional, geographical and matrix structures before globalisation. Organizations during the last quarter of the 20th century inter-weaved the organic/ humanistic principles in place of mechanistic principles to bring an apt fit between structures and strategies. But organizations could not find appropriate fit between these structural approaches and the strategies formulated after globalisation.

As such the companies started structuring flat structures, team-based structures, strategic business unit structures, empowered structures and virtual structures, adaptive/mobility structures, flexible structures, decentralised structures and externally focused structures during the post-globalisation period. Organization design based on these approaches result in broad banding characterised by a few levels, empowerment of employees, payment based on individual/team performance, horizontal reinforces, and few rules (Rastogi, 1998:45-46). In addition, companies with multiple portfolios also started adopting different structures for different portfolios of the organizations rather than one structure for the entire company. As such the human resource management implications vary from one portfolio to another portfolio of the same company. Further, human resource management policies and practices also vary from one strategic situation to another strategic situation. For example, Government of India allowed the establishment of private sector banks after 1991 as a

part of the process of globalisation and liberalisation that in turn created a problem of severe competition to the existing public sector banks like State Bank of India, Syndicate Bank, Indian Bank and Punjab National Bank. These banks formulated a low cost strategy in order to meet the competition from the private sector banks. As a part of implementation of this strategy, these banks de-layered their organizations by closing regional offices. In fact, information technology provided an opportunity of coordinating the branch offices by making most of the operations that were hither to performed by the regional offices redundant. In addition to de-layering, these banks also downsized their operations as a part of implementation of low cost strategy. Consequent upon de-layering and downsizing, these banks had to change their organization structures. These decisions resulted in retrenchment of surplus human resources in the name of golden hand-shake/voluntary retirement, providing new skills to sizeable employees owing to redundancy of certain skills(Human Capital,2000:18), mobility of a significant number of people to the new jobs consequent upon change in organization structure along with the introduction of information technology on massive scale and expansion of mutual funds portfolio of these banks and creation of new portfolios like issue management, housing finance and the like . Similar examples are also drawn from the banking industry of Papua New Guinea.

The process of globalisation, liberalisation and privatisation   in Papua New Guinea which was initiated in 1986 helped the Bank of South Pacific (BSP) to acquire a public sector bank viz., Papua New Guinea Banking Corporation (PNGBC) on 10th April 2002 , despite the huge opposition from the employees of the latter. Bank of South Pacific acquired and absorbed Papua New Guinea Banking Corporation in April 2002. by bringing major changes in the latter's organization structure. Some of the PNGBC employees were retrenched and some other employees were redeployed to various jobs in BSP. Consequently the size of employment of the Bank of South Pacific declined from 2099 in April 2002 to 1904 in December 2002 (Bank of South Pacific Annual Report, 2002:19) , despite the increase in assets from Kina 765.9 million to Kina 1799.2 million , deposits from kina656 million to Kina 1552 million, capital from kina77.4 million to Kina 146.5 million and net profit from kina18.9 million to Kina54.7 million during the period 2001 and 2002(Bank of South Pacific Annual Report,2002:30)

Thus, the shifts in organisational structure in case of public sector companies in these two countries occurred due to the fact that the Governments in both the countries either partly or fully shifted their responsibility of doing business to the shoulders of the private sector or shirked its responsibility of supporting the public sector organizations in carrying out their business followed by the globalisation which resulted in either retrenchment or redeployment or transfer of employees to lower level jobs. This process necessitated the individual employees affected by the structural shifts to acquire new skills, accept new jobs which carry different compensation packages, some times lower than the previous ones. Thus the HRM policies/practices of the companies were revamped towards the individualistic approach, which gradually affected the industrial relations process. Employees and trade unions, which were the significant actors of the traditional industrial relations neither opposed these moves of the management nor collectively bargained with the management effectively as the governments and managements, set their minds in tune with the challenges of globalisation. In fact, the other significant actor of the traditional industrial relations i.e. government shifted itself to the management side as it relinquished its basic philosophy of custodian of employees for the competitively high growth rate of industrial development of the country, compared to other countries.

The situation of structural shifts is more dramatic in private sector compared to that of public sector, consequent up on strategy shifts and the environmental sensitiveness. Coca-Cola followed the brown-field strategy in entering the Indian Market and as such acquired the manufacturing facilities of the existing bottling companies throughout the country without the obligation of retaining all the employees of these bottling companies. This resulted in retrenchment, redeployment, re-training, salary-cut and/or demotion for poor-performers and abnormal salary hike and /or promotion for high-performers. Employees /trade unions of the former bottling companies could not play their due roles as they hither to played before globalisation. According to the trade union leaders of Coca-Cola India Limited, Hyderabad Unit, it is mostly due to the fact that management created the fear of loss of jobs in the minds of employees and thereby followed the individualistic HRM approach. According to the Regional Human Resource Manager, Coca-Cola India follows individualistic HRM approach due to frequent structural shifts in the wake of severe competition from Pepsi-Cola.

Similar incidents are also common in case of Indian private sector companies in view of competition from national as well as multinational companies. Companies in sun-setting industries group like Panyam Cements Limited restructured its organization by downsizing its operations in order to cut the costs due to sever competition based on cost. This strategy resulted in retrenchment, hike in work-load, out-sourcing and long-working hours. Tata Electricals and Locomotives Limited, Viskhapatnam Steel Plant of Steel Authority of India Limited also follow the individualistic HRM approach due to the structural change and implementation of turn-around strategy consequent up on globalisation. Individualistic HRM approach in these organizations also made the trade unions defunct unlike before globalisation (Business World: 1989:54).

Revamping organisational restructures and shifts in the structures are relatively more volatile in the software industry as its environment depends upon its cliental organizations, their structures, level of technology, etc. In fact rate of change of technology is highest in software industry compared to other industries. In addition either out-sourcing or being out-sourced is quite common in software industry that led the companies of this industry to design their organization structures based on virtual structures and /or flexible structures. The flexible structure in variably results in flexible-cum-individualistic HRM approach while the virtual structure result in either non-commitment or insignificant commitment to the human resource aspect of total operations management.

Thus the implementation of competitive strategies consequent upon globalisation led to structural shifts in varying degrees in different types of business firms i.e., public sector, private sector, national, multinational, large, small, sun-setting, maturing and sun-raising resulting in the creation of new organisational structures like team structures, virtual structures, flexible structures etc. These new structures created an opportunity to the managements to deal with the employees individually in employment, development and compensation. But at the same time these structures require the employees to work in temporary and flexible teams in contributing to the achievement of the strategies efficiently. In turn the HRM policies and practices took paradigm shift from the individual contribution to team contribution as employees work in a team as lines of commands and control are wiped out in the team/flat/virtual structures which would result in synergy in case of employees' contribution to the organization is concerned. These structures also result in the shift of collectivistic HRM approach to the Individualistic HRM approach in case of employing, developing and compensating the employees which is in contrast with the HRM structure and practices followed before globalisations.

Job Design

The next significant aspect of in human resource management is job design and analysis. Traditionally jobs were designed based on engineering approach and later based on the humanistic and job characteristic approaches. These approaches led to narrow jobs, which did not fit in the framework of post-globalisation business strategies. Consequently companies started re-designing the jobs based on job bandwidth, which is based on employee multi-skills and empowerment, and horizontal reinforces. Further, some companies found that team design rather than job design has appropriate fit to the post-globalisation business strategies, resulting in de-jobbing (Vikram Chhachi,1996).

Team design and de-jobbing consequent upon employee multi-skills lead to surplus of workforce and thereby resulting in retrenchment, flexible work and work sharing barring the traditional formal communication channels and lines of command (Team Power, 2000:34). Employees learnt how to adept themselves to these shifts in job design due to fear of loss of job or cut in compensation package. In addition, organizations also provided training and facilitation programmes and enabled the employees in acquiring multi-skills and to cope up with the new demands of competitive and challenging strategies.

Dr. Reddy's Laboratories in India before introducing business process reengineering in 1998 indicated the possible consequences and demands on employees and enabled them individually to cope-up to the new demands ignoring the trade aurous. All the employees geared up to the requirements of the business process reengineering like teamwork, multi-skills, flexible work, work-sharing etc. The organization could implement the business process reengineering with no difficulty from the employees side. Thus trade unions-an important actor of industrial relations was ignored in this process.

Some Indian organizations like State Bank of India and Life Insurance Corporation of India formulated the retrenchment strategies like transformation through computerization before globalisation. Trade unions did not allow the managements to implement the strategy through various techniques of industrial conflicts. (Business To-day, 1984:16). However, these organizations could implement these strategies smoothly after globalisation that resulted in massive shifts in job design, job description and job specification. In addition, broad–banding replaced narrow jobs and team design replaced job design to a greater extent. Consequently a number of employees were retrenched through voluntary retirement scheme and other employees were trained and redeployed. Thus these organizations could implement the strategy and redesigned the jobs as the globalisation process made the trade unions and other actors of industrial relations defunct, by upholding the organizational interest.

Change in the job design is quite normal in the software industry like WIPRO, Infosys and Tata Consultancy Services Limited and the young employees in this industry do automatically change their mindset and skills depending upon the skill requirements owing to the threat of loss of job or lower salary. In fact, software industry that emerged mostly after globalisation is a non-union industry. Thus globalisation resulted in significant shifts in job design to de-jobbing, multi-skilling and employee empowerment. These paradigm shifts

in job design enabled the teamwork and resulted in synergy in case of human resources contribution to the organization.

Human Resource Planning

Globalisation along with information technology enabled the production technology transferable from country to country easily and at a fast rate. Consequently, organizations started concentrating their strategies around technology that were hither to concentrate around human resources before globalisation. Thus, organizations reduced their emphasis on human resource planning but increased emphasis on technology planning as a part of their strategic planning. Organizations like Satyaun Computers, Wipro and Infosys shifted their human resource planning from number of and kind of employees to internal skill mobility planning. The traditional industries like Indian Railways, Tata Iran and Steel Company Limited in India and Eda Ranu in Papua New Guinea plan for outsourcing rather than plan for human resources exclusively for them. Major Indian Railway trade unions viz., All India Railwaymen's Federation and National Federation of Indian Rail-workers, which were volatile in protecting employee interest before globalization became silent when Indian Railways planned for outsourcing certain operations, like catering and sanitation in railway stations.

Human Resource planning function was under the influence of trade unions before globalisation as the latter had been insisting on the less number of working hours, short shifts duration. In addition, Government of India had been influencing the managements of public and private sector companies in planning for recruitment of candidates from certain communities in their human resource planning, as a part of its reservation policy. But, the Government after globalisation stopped influencing the private sector in this regard as a part of its strategy of attracting foreign investment.

Thus globalisation has been contributing to the shifts in human resource planning like planning for skill-mobility and outsourcing plan. In addition, globalisation either minimized or eliminated the influence of two actors of industrial relations viz., trade unions and government on human resource planning.

Employment Practices

Domestic business environment has become more volatile due to the foreign direct investment, technology transfers, fast expansion of the operations of multinational companies and translational companies, mobility of the human resources, dispersion of manufacturing facilities with the help of information technology and soft political and economic policies of the governments towards foreign companies owing to globalisation. These developments in variably reduce the gaps between national business environment and international business environment. Added to this, the global companies have learnt how to produce, market and operate like a local company in various countries they operate, by acquiring the characteristic of local companies i.e., having the strengths of a global company and operating like a local company. These factors magnified the competition between multinational companies and domestic companies and made both the companies to formulate and implement strategies and counter strategies by acquiring competitive abilities and distinctive competencies at a fast rate (Dhawan Radhika, 1996:62-64). Of late, these companies realized that the appropriate human resources both in terms of hard skills and soft skills bring the distinctive capabilities in production, finance, marketing and other areas. Consequently, they started developing appropriate techniques in employing right human resources at a fast rate rather than relying heavily on traditional techniques of recruitment and selection.

The most important such recent techniques of recruitment followed by many sun– raising companies such as Zee Telefilms Limited, Global Trust Bank Limited, Satyam Computers Limited, and Bio-technologies Limited in India and Deltron, Datec and Global Technologies in Papua New Guinea is ' Employees Referrals'. Employees referrals is requesting the present employees to recommend prospective employees and motivating them to apply as the latter are well aware of hard and soft skills of the candidate (s) they refer and also the job and organizational requirements. Present employees provide information of most suitable candidates as it determines their credibility in the company. These shifts in the recruitment practice reduced the importance of trade unions and also Government in addition to relying upon the lengthy selection procedures of the past.

Other shifts in the recruitment practices include walk-ins, consult-in, head-hunting, body shopping e-recruitment and outsourcing. All these new practices help the companies to formulate and implement strategies fast and efficiently in the dynamic environment. Organizations, of late discovered that the soft skills compared to hard skills of employee determine the employee's efficiency on and contributions to the job and thereby to the achievement of the competitive strategies after globalisation. As such organizations started emphasizing on testing the candidate's aptitude, attitude, emotions and interest. In fact, Infotech Limited discovered and realized that the employees with positive attitude take-up the activities willingly on their own and they acquire the

necessary skills, if they do not possess them (Subbarao, 2003,:103),commit themselves to the organisational goals and strategies and thereby towards their individual goals rather than looking for trade unions or Governmental agencies for help. In the words of Regional Human Resource Manager, Andha Pradesh Region of Coca–Cola India Limited, such employees not only eliminate the unnecessary intervention of trade unions, but also reduce the amount of supervision and enhance productivity.

The complex strategies led the organizations to select the candidates and employ them with multi-skills rather than expert skills in one area. Some of the companies like L&G in India, Larsen and Toubro Limited's cement works division in India realized that most of the company operations up to a certain level could be performed by majority of the employees, if required basic skills are provided through formal or informal training. As, such L&T started selecting the candidates with basic multi-skills and developing them and empowering them. These employees, always look for a change and thereby not only pro-act to organizational requirements, but also fully commit themselves towards the achievement of organizational strategies. These employees do not have need for or time to think of trade unions or government for support, as organizations never find a chance to victimize them. In addition, the other shifts of selection like on-line selection tests and on-line interviews enable the companies to reduce the cost of and time duration in this process.

Performance Appraisal

Other significant area in human resource management is performance appraisal. Performance appraisal techniques were traditionally used to punish the employees and then trade unions used to interfere in the management's decisions and actions and protect the employees. Of late, organizations started using performance appraisal ratings for identification of employee weaknesses and initiate training and development programmes in order to develop employees that in turn reduced the role of trade unions.

360^0 performance appraisal is another major shift in performance appraisal area that enables the employees to have all-round feedback and to initiate the steps to correct and develop themselves to contribute efficiently for strategy implementation, as is the practice in Coca-Cola India and Larsen and Toubro Limited. Other performance appraisal shifts include: developing performance measures to assess the value addition of human resource contributions as adopted by Royal Dutch Shell, measuring employee involvement in key corporate functions as adopted by KPMG Peat Mar Wins and Federal Express (Subbarao, 2003: 138), aligning performance systems with strategies, creating internal performance consultants to define benchmarks along with employees, analyse performance and enable the employees to attain it. These shifts aim at enabling the employees to understand the strategies, acquire necessary skills to contribute to the achievement of strategies and develop confidence in attaining the benchmarks (Sharma, 2000:29). Thus shifts in performance appraisal also eliminated the influence of trade unions and tend to follow individualistic approach to HRM.

Human Resource Development

Traditionally trade unions and collective bargaining institution were less concerned with training and development aspects of human resource development. In fact, managements have been concerned much with these aspects as employee contribution to the organizational strategies depends on how efficiently they are imparted with necessary skills, knowledge and aptitude. There is no phenomenal shift in the role of industrial relations institutions in this regard even after globalisation, as their role was and is dismal before and after globalisation. But trade unions and governments as actors of industrial relations were/are concerned with the career planning and development aspect of HRD (Rao, T.V.,1991:21) The managements during the post-globalisation era take interest in career planning and development of those employees whose skills are in demand. As far as career planning is concerned most of the companies belong to sun-rising and maturing industries in India are going for contract staff rather than concentrating on career planning due to the advantage of the former over the latter. Thus the globalisation resulted in excessive dependence of the companies on contractual staff rather than regular staff that reduces the budget on human resource development as is the practice in Larsen and Toubro Limited in India and Eda Ranu in Papua New Guinea. Contract staff takes care of their training and development by themselves (Human Capital, 2001:48). Further, they never become the members of company trade unions. Thus globalisation, in this respect contributes for the decline in membership of trade unions and thereby their finances and activities.

Salaries And Benefits

Government of India before globalisation favoured socialistic pattern of society and consequently minimization of inequalities in the distribution of incomes and salaries. In fact, these were the trends in the erstwhile socialistic and communistic countries before globalisation. But, the market economies around the globe disfavoured these trends and set a new trend for wage differentials in order to attract high skilled and talented employees (Human Capital, 1999:16). In addition, market forces determine the price for all resources including human resources. Thus globalisation results in higher salaries and benefits for those employees whose skills are in scarce supply and lower salaries for those employees whose skills are in abundant supply (Human Capital, 2001:18).

In addition, globalisation also set trends for adjustment of salaries based on performance. As such different employers working on the same job get different salaries based on their performance levels, as is the case with Coca-Cola India, Infosys, Satyam Computers and Wipro in India and Daltron, and Global Technologies in Papua New Guinea. Thus salaries and benefits vary from employee to employee based on their performance levels and demand and supply factors. However, public sector is an exception to this shift. Consequently individual bargaining based on demand and supply factors displaced the collective bargaining in this regard also paving the way for individualistic HRM. However, salary increase has become a rare phenomenon in public sector after globalisation.

SUMMATION OF IMPACT ON HRM

The above analysis indicates that globalisation resulted in paradigm shifts in human resource management in various sectors in varying degrees and nature. Large scale private sector which has been exposed to international competition directly and small scale private sector which exposed to domestic competition directly and global competition indirectly experienced paradigm shifts in human resource management viz., down-sizing, de-layering, virtual organizations, team design, outsourcing, de-jobbing, employee empowerment, development based performance appraisal, on-line training, employee-based training, salary based on performance and demand and supply factors, and the like which resulted in the individual employee based human resource management in case of employment, training, development, and compensation and team based human resource management as far as employee contribution to the achievement of organisational strategies is concerned. These paradigm shifts invariable have their impact on industrial relations, as industrial relations are the outcome of the human resource management.

Impact Of Globalisation On Industrial Relations

Industrial relations deal with the relations among workers and their unions, management and their organizations and the state. As such the three important actors of industrial relations are the workers and their organizations, employers and their organizations and the Government (Dunlop, John T. 1958: viii). The interactive and dynamic roles played by these crucial actors in the process of protecting the interests of workers and companies in a balanced and mutually exclusive manner created a number of industrial relations institutions including collective bargaining, machinery to prevent and settle industrial disputes and participative management. Traditionally, these actors and institutions of industrial relations had been expected to maintain industrial peace and to secure unreserved cooperation and goodwill among different groups in industry with a view to drive energies and interest towards economically viable and socially desirable channels. It also aims at the development of a sense of mutual confidence, dependence and respect and at the same time encouraging them to come closer to each other for removing misunderstanding, redressing grievances, if any, in a peaceful atmosphere and with open mind and fostering industrial pursuits for mutual benefits and social progress (Subbarao: 1999:494-495).

Trade Unions

The commodity approach towards labour and machinery concept of labour together with the management's exclusive concentration on their goal of profit maximization by exploiting labour resulted in the formation of trade unions to remind the management to aware of their responsibilities towards the most important and living resource of the organization i.e., human resource. Thus the trade unions were emerged to protect the employees' interest.

Trade unions across the globe had been recognised as legitimate social and economic organizations of employees and have become part and parcel of industrial organizations as a vital organ of industrial relations. Trade unions aim at achieving various objectives primarily protecting the economic and social interests of

employees and as such they have helped workers in getting higher economic gains, sometimes without enhancing employee contribution to the organisational goals. They have also succeeded in unionising workers in small business entities.

Trade unions have undergone serious stresses, negotiated with managements and sometimes fought against employers by organising strikes and by threatening managements in order to achieve the demands of workers. They adopted various strategies to safeguard workers' interests including representing the workers' issues to the management, negotiating in the collective bargaining, organising strikes, enforcing political pressures etc. As such, management of most of the companies could not make unilateral decisions before globalisation that might have affected employee-employer relations directly or indirectly, positively or negatively. Further, management were restricted in the areas when they could take decisions about human resources management independently of the trade unions as the latter became more sophisticated and professional. Thus, unions before globalisation became employer-regulating device and sought to regulate the discretion of employers at every point where their action might have affected the welfare of employees. Trade unions questioned, criticised, challenged, modified and regulated even the corporate strategic decisions particularly those affected the employees before globalisation.

Trade unions, thus, played a vital role in protecting employees' interest and a devil's advocate role for managerial decisions and actions, before globalisations. This is true in case of all kinds of Indian organizations (public sector, private sector and small industries) like Indian Railways, Indian posts, Hindustan cables Limited, Anhra Prsdesh State Road Transport Corporation, Tata Electrical and Locomotive Company Limited and Andhra Pradesh Lightings Limited and organizations in Papua New Guinea like Air Niugini, PNG Telekom, and the erstwhile PNG Banking Corporation. The situation of protective and welfare economics strengthen the trade unions in terms of membership, finance, organization and militant strategies and political leadership and enabled them to fight against managements of various companies, some times leading to organisational dysfunctional and chaos.

Globalisation along with the deregulation of economies led to severe competition among businesses and placed the customer first by displacing the position of employees and made the latter and their unions to realize that they are also for customers along with management but not vice-versa. This situation led to the employees to realize that they have to protect themselves and serve the customer most efficiently by developing skills and positive attitude. The able employees came out of the shadow of trade unions, acquired new skills, realized their potentialities and have grown beyond the expectations of their own as well as organizations through their individualistic approaches.

The globalisation process forced the governments and political parties to withdraw their support to trade unions. As such trade unions could not protect the interest of less skilled employees from loss of jobs when organizations downsized their operations and retrenched the less able employees and finally became lean in membership, finance, organization and leadership. Even the largest employees' federations in India like all Indian Trade Union Congress and Indian National Trade Union Congress and in Papua New Guinea like Communication Workers' Union, Financial Workers Union etc. tend to reach this stage. As such, it is needless to mention the situation of regional and organisational level trade unions. Thus trade unions tend to reach the stage of decline. It can be said that the capitalistic and globalisation trends drive the trade unions in a reverse gear. The decline of trade unions in variably has its impact as the functioning of collective bargaining.

Collective Bargaining

Collective bargaining is a process of negotiations about the terms and conditions of employment between employer and a group of employees or one or more trade unions with a view to reaching an agreement (International Labour Organization, 1957: 3). There has been evident that trade unions and management of almost all the public sector organizations and large and medium private sector organizations used to negotiate on terms and conditions of employment and arrive at agreements and consequently notify human resource management policies and strategies based on the collective agreements. Collective bargaining in Indian Railways, Indian Posts etc. has been a continuous process under the permanent negotiating machinery. Similarly, collective bargaining in private sector industries like Southern Pesticides Limited, Navabharat Ferro Alloys Limited and Nizam Sugars Limited in India was also a continuous process. Collective bargaining before globalisation played a vital role in settling the terms and conditions of employment, though minor issues of individual employees which had no bearing on other employees were redressed through the grievance procedure in most of the Indian organizations. This is also the case with PNG Telekom Limited, erstwhile PNG Banking Corporation, Eda Ranu, etc. in Papua New Guinea. Thus, the collective bargaining was instituted and functioned with a certain degree of effectiveness mostly due to the fact that terms and conditions of employment were common at least for a group of employees and the trade unions had the power to modify human resource policies formulated by management in each company before globalisation.

The post-globalisation scenario tends to drive collective bargaining in a reverse direction as terms and conditions of employment vary from employee to employee and the power of trade unions in modifying management's decisions was drastically revamped . The decaying trend of trade unions and /or emergence of non-union organizations during the late 1980s contributed to the shift from collective bargaining to individual bargaining in private sector. Dr. Reddy's Laboratories, Ushodaya Publications Limited, Eicher Tractors Limited, Satyam Computers switched over to individual negotiation during the post-globalisation era. However, the public sector industries like Indian Railways, Bharat Heavy Plates and Vessels Limited, Visakhapatnan Steel Plant of Steel Authority of India Limited, and Hindutan Cables Limited still continue collective bargaining in certain minor issues in principle as the terms and conditions of permanent employees are common. Similar trends are also observed in public sector undertakings of Papua New Guinea.

The competition from domestic private sector industries and multinational companies forced the public sector to adopt retrenchment and restructure strategies. For example, Viskhapetnam Steel Plant of Steel Authority of India Limited, Hindustan Cables Limited and Bharat Heavy Plates and Vessels Limited adopted down sizing and turnaround strategies. Consequently they retrenched redundant employees, outsourced certain employees' functions, trained and developed the partially redundant employees without negotiating most of these issues in collective bargaining. Thus management tend to take unilateral decisions in these areas without negotiating in collective bargaining meetings. Collective bargaining with regard to vital issues even in public sector took the shift to individual bargaining along with that in private sector.

Thus bargaining is phenomenally shifted to individual bargaining from collective bargaining in private sector and to a considerable extent in public sector. The fundamental changes in trade unions and collective bargaining invariably bring the shifts in nature and degree of industrial disputes.

Industrial Disputes

Though several measures are taken to manage human resource, satisfy the demands of employees and employer, disputes between employees and employer take place due to conflict of interest between capital and labour. The collective forms of industrial dispute like work-to-rule, strikes by all or a group of employees, lay-offs and lockouts were common before globalisation. Indian newspapers and magazines were publishing the news items of industrial strikes and lockouts prominently before 1990s, but could not do so later. It is quite abnormal to listen to strikes and lockouts in India as well as Papua New Guinea public, private, large and small-scale sectors after globalisation. This is mostly due to the individualistic approach adopted by the business in managing their human resources. Under this approach, employee quits the job on his own, if he is dissatisfied with the terms and conditions of employment and the management terminates the services of individual employee, if it is not satisfied with employee contributions and /or discipline. This is just and a simple way of solving the employee-employer disputes and terminating their relationships. These trends have become more prevalent in various private sector organizations like Satyam Computers, Infosys, Larsen and Toubro Limited, Coca Cola India and Tata Consultancy Services Limited. However, public sector organizations like State Bank of India, Hindustan Cables Limited, and Hindustan Petrochemicals Limited introduced the voluntary retirement scheme and enabled the employees to quit the organization on their own. But, they are still unable to terminate the service of unwanted/ redundant employees due to the nature of the organization. Bank of South Pacific, Eda Ranu , Telekom PNG Limited etc., terminate the services of unwanted or redundant employees easily. In fact Papua New Guinea organizations mostly follow the contractual employment even for the nationals. Thus, manifestation of conflicts took a reverse direction in all organizations in PNG and private sector organizations in India and a mid–way direction of docile nature in Indian public sector organization during the post-globalisation era.

Participative Management

The next important institution of industrial relations is the worker's participation in management. The concept of workers' participation in management crystallizes the concept of industrial democracy, and indicates an attempt on the part of an employer to build his employees into a team which works towards the realization of a common objective (Kesari, 1971: 4). Some of the public sector organizations and a few private sector organization adopted different schemes of workers' participation in management like Works Committees, Shop Councils, Joint Councils and Joint Management Council before globalisation. However, these councils or committees could not function efficiently mostly due to non-cooperation of the managements which were of the view that workers lack managerial abilities and they encroach the management and ownership of the firm as India was a socialistic pattern of society before globalisation.

But globalisation and economic liberalisations changed the direction of Indian and PNG economies towards market economies. Competition, consequent upon globalisation forced the managements to realize that human resource offers them a distinctive competency. As such managements to day encourage the employees to participate in decision-making, share their ideas and knowledge, disseminate the information they acquire at workplace and empower them by developing multi-skills to make decisions on their own. Globalisation led to optimum utilisation of human resources through participative management approach and contributed to the attainment of the goals of workers' participation in management idea which was hither to failed before globalisation. Thus globalisation tends to drive the operation of if not the theme of workers' participation in management in reverse direction.

CONCLUSION

The analysis of impact of globalisation on human resource management structure and on industrial relations pattern indicates that globalisation brought paradigm shifts in human resource management structure and pattern in both the countries understudy with varying degrees like de-layering, team and virtual structures, downsizing, multi-skilling de-jobbing, more weighages on employee soft skills like attitudes, emotional intelligence and the like in employee selection, outsourcing of human resource, on-line training and employee's own initiatives for self development, use of performance appraisal for employee development, compensation based on demand, supply factors and performance levels of each employee and the like. These paradigm shifts changed the traditional collective approach of human resource management to individual approach of human resource management in case of employment, development and compensation and team based structure in case of employee utilisation.

These paradigm shifts in human resource management structure brought fundamental change in industrial relations institutions and pattern. The major actors of industrial relations have been either made defunct or tend to withdraw from their respective roles and consequently only employees and employer remain to play their roles in industrial relations which was similar to pre-1920s periods of Indian industrial relations scenario and the early stage of industrial relations in Papua New Guinea. Similarly the important institutions of industrial relations like collective bargaining, Welfare Officers, Bipartite and Tripartite bodies became irreverent and redundant as employer directly deals with individual employees based on market forces and/or employee performance levels after globalisation with minor exceptions. However, the institution of Workers' Participation in Management, which could not function efficiently before globalisation, started functioning in its idea-form efficiently after globalisation due to the competitive environment.

Therefore, it is viewed that globalisation provides free and deregulated environment to the business to operate, which in turn resulted in severe competition and formulation of competitive strategies. This competitive situation forced the companies to develop competency building-cum-low-cost centred human resource strategies. These strategies demand for getting highest human resource productivity at the lowest possible cost. The efficient implementation of new human resource management strategies demanded a non-regulative environment from the industrial relations institutions paving the way for a fundamental change in industrial relations system. Thus globalisation tends to bring significant shifts in HRM i.e., from collective to individual HRM and thereby a fundamental change in Industrial relations i.e., collective relations to individual relations.

In contrast, communistic/socialistic economic systems before globalisation along with closed economies made the governments to act as the custodian of the nation and establish welfare institutions and demanded both the public and private sector industries to formulate welfare-centred corporate level and human resource strategies. Consequently a number of industrial relations institutions came in to being and checked and controlled the implementation process of employee protection. Thus Industrial relations institutions find a significant role to play in communistic/socialistic economic systems.

Therefore, it is viewed that the communistic/socialistic economic systems (closed economies) result in protective human resource management structure and thereby collective and welfare-centred industrial relations and capitalist economic systems (global economies) result in competitive human resource management structure and thereby individual and contingency based industrial relations.

ABSTRACT

The main purpose of this study was to examine the significant relationship between job rotation and employee career development among production workers. A model of job rotation developed by Campion, Cheraskin and Stevens (1994) was used as the premise to test the linear relationship between job rotation and employee career development outcomes that are career progression, knowledge and skill and career management. This is done by analyzing survey-based data sets particularly obtained from samples of 209 production workers in Japanese electronic manufacturing companies operating in Malaysia. The Pearson Correlation was used to measure the association between the variables and to test the research hypotheses. The results of the study reveal that there were significant correlation between job rotation practices and three career development outcomes, namely, career progression, knowledge and skill and job rotation benefits. The practice of job rotation in the workplace has played an essential role in employee development and can provide a lot of opportunities for employees to gain necessary skills and knowledge for future advancement. Job rotation is considered as an important on-the-job training and first emphasis must be given in designing and implementing job rotation program systematically for all level of employees.

INTRODUCTION

Job rotation refers to the systematic movement of employees from job to job or any change in assignment or responsibility on the premise to enhance employees' experience in the jobs (Kirk et al., 2000; Olorunsula, 2000; Khairul Aidil et al., 2000; Campion et al., 1994; Thamhain, 1992). Job rotation is one of career development intervention that has been used in providing employees with good foundation for developing their career in the workplace. The practice of job rotation has long been espoused in various human resources management area such as employee learning, career satisfaction and interpersonal effectiveness (Susan, 1996; Campion et al., 1994; London, 1983). Even though a great deal of studies have addressed the issues of job rotation from specific areas of human resources management, only a few studies have investigated the influences of job rotation practices on employee career development in the workplace (Campion et al. 1994; Ortega, 1999). However, there has been no attempt to examine the issue of job rotation and its relationship to employee career development especially among workers in Japanese manufacturing companies in Malaysia (Raduan, 2002; Lai Wan, 2001).

The main purpose of this study is to examine the significant relationships between job rotation and career development among production workers in Malaysia. The specific objectives are:

  i.   To determine the relationship between job rotation practices and career progression;
  ii. To determine the relationship between job rotation practices and knowledge and skills; and
  iii. To determine the relationship between job rotation practices and career management

The implementation of job rotation practices can be seen in the case of Japanese firms (Cosgel and Miceli, 2000). One element that appears to be fundamental of the Japanese model of human resources management (HRM) is the characteristic of flexibility Japanese firms, which depends on multiskilled employee. According to Koike (1984), job rotation was practiced in Japan as early as the late 1950s and hold true for all employee in many Japanese firms. In view of human resource management, many researchers have described job rotation in broader areas. For instance, Noe and Ford (1992) described job rotation as opportunities for employee to gain a broader knowledge of different functional areas and to develop a network of organizational contacts.

LITERATURE REVIEW

Job Rotation And Career Development

Kirk et al. (2000) defined career development as a process for achieving specific employees and organisation goals, which include providing career information to employees, helping employees identify advancement opportunities and promoting job satisfaction. Likewise, career development program also can be used to sustain or increase employees' current productivity and to achieve a balance between the individual's career needs and the organisation workforce requirements (Leibowitz et al., 1986). In other words, career development activities can help employees discover their vocational interests and strengths, whilst, employers can make it as a way to attract the best employees and retain them over time.

A study by Wright and Belcourt (1994) noted that on-the-job training is the primary vehicle for employee development in the organisation. They suggest that learning from experience or learning by doing such as business simulation and job rotation can enrich employees' development opportunities. This argument is made based on the premise that exposure to many functions within the organisation can provide them with multiple areas of expertise.

Career Progression

With regard to career progression, Campion et al. (1994) classified employee career progression into two dimensions, which include promotion and salary growth. According to Indahwati and Brian (2001), promotion in a business organisation can be defined as a management practice for recognizing and rewarding employee effort and contribution to the organisation. It is usually represented with a change of job and title and can be attached with an increase in pay, power and responsibility. Marian et al. (1995) also suggested that promotions to jobs provide the job challenge to employee with new responsibility and work contents. In most organisations, promotion decisions are generally made on the basis of seniority or ability or both (Indahwati and Brian, 2001). As a mean of relating promotion systems to job rotation practices, ability can be defined as a combination of skill, knowledge, attitude, behaviour, performance, production and talents.

Knowledge and Skills

According to Sally (1997), most people have a common understanding of skill but defining precisely what is meant by skill is problematic. Historically, skill has been associated with being skilled, having gone through a long period of training. Some researchers demonstrate through empirical research that knowledge and skills are frequently used as a basis for employee development (Tesluk and Jacobs, 1998; Uzoamaka et al., 2000). For example, Tesluk and Jacobs (1998), addressed knowledge and skill development as the direct outcomes of work experience. Several researchers have also classified various types of skills that are associated with on the job experience (Campion, et al., 1994; Thamhain, 1992; Burke and Moore, 2000). For example, Campion et al. (1994) mentioned knowledge and skills outcomes into administrative knowledge, technical knowledge and skills and business knowledge. Their findings suggest that knowledge and skills were improved by job rotation. Employees with high rates of rotation perceived greater improvement in various disciplines of knowledge and skills. These dimensions of skills also indicated in the study by Thamhain (1992) in an effort to examine engineering management skills, which included an enhanced of administrative skills, namely, ability to organize multifunctional program, attracting and holding quality people and so forth.

Career Management

The concept of career management can be defined in various ways. For example, Noe (1996) in his study on career management in the information technology sector defined career management as career exploration, development of career goals and career strategy implementation. Meanwhile, according to Christopher (1994), individual career management refers to the employees efforts to advance their own career goals. This effort is made in order to maximize career development provided to satisfy their personal career goals and achievements. For the purpose of the study, career management refers to the benefits and costs that association to the job rotation practices in the workplace (Campion et al., 1994). Essentially, individual career management outcomes here refers to the process of identifying what the benefits and costs that relate to job rotation in order to help employees in determining what steps to be taken to realize their career goals.

RESEARCH FRAMEWORK

The theoretical framework for this research was adapted from the Campion et al. (1994) model, which described the relationship between job rotation and career development outcomes inside the finance department of a large United State pharmaceutical company (illustrated in Figure 1). The primary variable of interest in the study was the independent variable of job rotation. The conceptual model classifies the job rotation practices according to employee interest. The model also suggests that employee career development outcomes, namely, career progression, employee knowledge and skills and career management are the dependent variables or potential outcomes that have been identified as associated with job rotation.

Figure 1: Research Framework for Job Rotation and Employee Career Development

Source: Adapted from Campion, Cheraskin and Stevens (1994:26)

METHODOLOGY

Research Instruments

Four indicators were used in the study to measure the constructs of interest. They included measures of the job rotation practices, career progression outcomes, knowledge and skills and career management.

Measurement of job rotation

Job rotation was measured using employee interest towards job rotation, adapted from Campion et al. (1994). Self-reported interest in job rotation was measured by employee interest in general and it was measured with a four (4)-item interval scale. For instance, "I am generally in favour of job rotation for training and development".

Measurement of career progression

Career progression is indicated by employee perception towards promotion opportunity within an organisation. Perceptions of promotion opportunity were assessed with a six (6)-item scale constructed by Marian et al. (1995). Sample items in the interval scale type include, "Job rotation creates an environment that enables me to grow in my career"

Measurement of knowledge and skills

For the present study, knowledge and skills related to job rotation practices were assessed using three indicators namely, administrative knowledge, technical skills and business knowledge. The administrative knowledge were assessed with a five (5)-item scale and both the technical skills and business knowledge were measured with a four (4)-item scale adapted from a work by Campion et al.

Measurement of career management

Career management is indicated with the benefits and costs of job rotation, all adapted from Campion et al. (1994). The benefits of job rotation were measured using four (4) categories (categorized as an interval scale), which include career effect, organisation integration, stimulating work and personal development. The costs were clustered into three categories which are workload and decrease productivity, learning curve, and satisfaction and motivation.

Population and Sampling

The target population for the present study is all the production workers in the Japanese electronic companies based in Malaysia. The database for the Japanese companies was extracted from main directories, namely, the Japan External Trade Organisation (JETRO) 2001, which provides a list of Japanese manufacturing companies operating in Malaysia. According to JETRO (2001) and Raduan (2002) there are 1346 Japanese subsidiary companies operating in Malaysia. Specifically, 722 of the companies were manufacturers and 624 non-manufacturers. The target population of production workers to be investigated in the study was restricted to 335 Japanese electronic companies in Malaysia (JETRO, 2001). In the present study, production workers refer to those working in a manufacturing production line, managing a production line and who reported to the Production Managers (Riding and Mortimer, 2000). Therefore, the sampling frame in the current study includes line operators, technicians, production line supervisors and group leaders (Raduan, 2002). The units of analysis were individuals.

Data Collection

The pilot study was conducted by distributing twenty-five samples of questionnaires at the SMK Electronics (Malaysia) Sdn. Bhd. Beranang Industrial Estate, Selangor. Out of 25 questionnaires distributed, 22 were returned and only 20 were determined to be reliable and used for analysis.

A total of 1500 questionnaires were distributed to sample of production workers in 335 of Japanese electronics companies in Malaysia by using random sampling. For each mailed questionnaire, a personalised cover letter was attached together with a reply paid self-addressed envelope for their convenience. A total of 225 questionnaires were returned to represent the sample of this study, which is a response rate of 15%. However, 16 responses were eliminated due to excessive missing data. Therefore, the reliable sample size for present study was 209.

Reliability

A reliability test was done on seven variables of interest, namely, job rotation, career progression, knowledge and skills outcomes (administrative, business and technical) and career management (benefits and costs). As shown in the Table 3.1 below, the Cronbach's Alpha obtained for job rotation was 0.7367, followed by administrative knowledge (0.8262), business knowledge (0.6943) and technical skills (0.6248). Meanwhile, the Cronbach's alpha for both benefits and costs was 0.9165 and 0.8366 respectively.

Table 1: Result of Reliability Analysis Test Based on the Alpha Scale

Variables	Number of Items	Alpha Value
Job Rotation	4	0.7367
Career Progression	6	0.8214
Administrative Knowledge	5	0.8262
Technical Skills	4	0.6943
Business Knowledge	4	0.6248
Benefits	18	0.9165
Costs	14	0.8366

RESULTS

Profile of Respondents

In this study, Table 2 below shows that most of the respondents were female (67.5%) as opposed to male (32.5 %). The total respondents were 209 production workers consisting of 141 females and 68 males. Female workers were make up the majority of production workers in Japanese electronic manufacturing companies, which accounts for 35% more than male workers. Further more, the majority of the production workers were aged 26 to 30 years (38.3%), followed by those aged 21 to 25 years (26.8%) and those aged 31 to 35 years (21.5%). As far as tenure is concerned, it showed that most of the respondents have been working with the company for one to three years (31.1%). The results show that 30.6%, of the respondents have been working for four to six years, followed by 29.2% of production workers who have been working for seven to ten years with the companies surveyed. Finally, the percentage of the respondents who have been working for ten years and more is the lowest at 9.1%. With respect to level of education, 36.4% of the respondents have SPM/STPM qualification, followed by diploma holder (11.0%) and degree qualification (1.4%). A total of 50.7% of the respondents did not managed to complete their lower secondary and/or primary education (lower than high school).

Table 2: Profile of respondents

PROFILE OF RESPONDENTS	PERCENTAGE (%)
1. Gender	
a) Male	32.5
b) Female	67.5
2. Age	
a) 16-20 years	4.3
b) 21-25 years	26.8
c) 26- 30years	38.3
d) 31-35 years	21.5
e) > 35 years	9.1
3. Number of years serving	
a) 1-3 years	31.1
b) 4-6 years	30.6
c) 7-10 years	29.2
d) More than 10 years	9.1
4. Level of education	
a) Lower than high school	50.7
b) SPM/STPM	36.4
c) Diploma	11.0
d) Degree/Bachelor	1.4
e) Others	0.5

Relationship Between Job Rotation And Career Development

Pearson Correlation was conducted between the job rotation and all dimensions of career development. The results were shown in Table 3. As seen from the results, all dimensions of employee career development were correlated with job rotation. Only costs outcome was not correlated with job rotation. With regard to correlation between job rotation and career progression, the results show that the job rotation practice is positively correlated with career progression at 0.01 confidence level and scored the highest coefficient correlation value (r=0.417).

The Pearson Correlation also proved that there is a significant relationship between job rotation and employee perception towards technical, business and administrative outcomes. The correlation coefficient value is 0.268 for technical skill, followed by 0.268 for business and 0269 for technical outcomes (p=0.00). Pearson Correlation was also conducted between the career management outcomes that is benefits and costs. As shown in Table 3, only benefits was correlated with job rotation (r=0.384). The results show that the job rotation is positively correlated with employee perception towards job rotation benefits at 0.01 confidence level. On the contrary, cost does not correlated with job rotation (r=-0.079).

Table 3: Results of Pearson Correlation between Job Rotation and Dimensions of Career Development (n= 209 Production Workers)

Job rotation	Correlations	sig. (1 tailed)
Career Progression	0.417**	.000
Technical	0.248**	.000
Business	0.268**	.000
Administrative	0.269**	.000
Benefits	0.384**	.000
Costs	-.079	.258

Note: ** $p \leq 0.01$ level (1-tailed)

DISCUSSIONS

The present study was set out to examine the relationship between job rotation and career development outcomes among production workers in Japanese electronic manufacturing companies in Malaysia. The data from 209 respondents was collected through a standardised questionnaire distributed to all respondents with the help of the human resource personnel in those companies.

Relationship Between Job Rotation And Career Progression

With regard to the relationship between job rotation and employee perception towards career progression outcome, the Pearson Correlation analysis found that there was a significantly positive correlation (r=0.417) between both variables. The finding had shown that production workers tended to perceive a greater interest in participating in job rotation, which is associated with their perception of getting promoted within the organisation. The relationship between job rotation and promotion opportunity was able to provide further support in suggesting that employees with a high level of interest in participating in job rotation are more likely to have a higher desire for a better position in the organisation. The positive relationship between both variables was consistent with the findings from studies by Campion et al. (1994) and Kusunoki and Numagami (1998), which confirmed that the rate of job rotation was significantly positively correlated with employee promotion as well as salary growth.

Relationship Between Job Rotation And Knowledge And Skills

Another objective of this study was to examine the relationship between job rotation and employee perception towards knowledge and skills outcomes. It was found that the overall link between job rotation and knowledge and skill perception was significant. It appears from the study that job rotation had significantly positively correlated with three categories of knowledge and skill outcomes which are technical skill (r=0.248), business knowledge (r=0.268) and administrative knowledge (r=0.269). However, this finding was not consistent with a study by Campion et al. (1994) which indicated a significant positive correlation for administrative and business skills, but not for technical skill.

Relationship Between Job Rotation And Benefits And Costs

With regard to the job rotation and its benefits relationships, the finding of the study shows that employees who perceived a greater interest in participating job rotation had reported greater benefits on its (r=0.384). Campion et al. (1994) noted that employee interest in participating in job rotation would influence their perception towards its benefit. Moreover, London (1983) indicated that employees who participate in job rotation might have a greater understanding on various scopes of job functions, duties and responsibilities.

This present study also attempted to test the relationship between job rotation and employee perception toward its costs. The Pearson Correlation test shows that job rotation does not correlate with employee perception toward its costs. In other words, employee interest in job rotation was not significant with their perceptions towards its costs. The finding was consistent with Campion et al. (1994), whom noted that employee interest and experience in job rotation had no effect on their perception toward its costs.

IMPLICATIONS AND CONCLUSIONS

Several implications for managers and executives may be drawn from the current research. Firstly, the research finding show that job rotation had significantly correlated with employee perception towards promotion opportunity. From this standpoint, human resource executives can draw a clear understanding of the essential influence of job rotation on employee promotion decisions. As suggested by Sullivan and Au (1998), job rotation provides an incentive to the organisation to promote workers form within, accompanied with the sets of skills needed for a higher-level position in the organisation. At the same time, job rotation provides information that the organisation can use to improve the allocation of jobs among employees. In other words, it may be easier for the management team to determine the most appropriate job for that worker.

Secondly, the emphasis on the knowledge and skill employed by employees in the workplace is also open for a new approach in designing and implementing job rotation practices. As suggested by Campion et al. (1994), organisations could more proactively design and manage job rotation as a main component of employee career development programs. In line with this, it is essential to note that job rotation should be managed as a main component of organisation OJT and career development systems. Human resource executives should have a clear understanding of exactly which skills can be enhanced by placing employees into the job rotation practices. In this effort, organisations should be able to address skills that are not enhanced by job rotation through other training programs like cross-training, coaching and various types of off-the job training.

On the other hand, several implications for theoretical contributions may also be drawn from the current study regarding job rotation and career development. Firstly, the positive correlation between job rotation and employee perception towards career development outcomes such as promotion opportunity and knowledge and skill outcomes indicated that there is a tendency among production workers to improve their current career in the organisation by actively participating in job rotation. Therefore, with regard to a model of career development developed by Wright and Belcourt (1994), job rotation can be used as a part of organisational strategy to improve employee core skills and self-development. According to this model, training activities needed to be taken according to the stage in the employee's career/position or the changing needs of both the organisation and individual. With respect to production workers, it can begin with a well-developed job rotation program for employees in early career (low tenure) and continue throughout their career in the organisation as a part of a career development process.

The practice of job rotation in the workplace has played an essential role in employee development. All employees in various manufacturing industries should be encouraged to actively participate in job rotation. With regard to the relationship between job rotation and career development prospects, it can be concluded that the practice of job rotation in the organisation can create a lot of opportunities for employees to gain necessary skills and knowledge needed in their future career. First emphasis should be given on educating employees about the importance of job rotation as part of their career development interventions. There is no point if the benefits from the practice of job rotation cannot be transformed into employee career development. As an effective means of developing employee career, it has become necessary for Japanese companies to perform job rotation among its employees

The Effects of Trainees' Attitudes and Perception of Support on Training Outcomes

Chong Siaw Fung
Actionpoint Professional Services Sdn. Bhd.
P O Box 16245
88869 Kota Kinabalu, Sabah
E-mail: csfung@pc.jaring.my

ABSTRACT

Training could be a costly investment with little assurance of returns. Thus, the issue of training effectiveness has remained significant for investment considerations of any organization. Earlier studies on training effectiveness and transfer dwelt a lot on factors related to training designs and conditions. However, towards the end of the 1980's, researchers began to show interest in the study of attitudinal and environmental factors that may affect training outcomes. This shift of focus reflects the realization among theorists and researchers that there are human-related and environmental factors that could have affected the learning and transfer process resulted from training experiences. In this study, a training course on 5S housekeeping practices in industrial operations is conducted for about 80 operations workers and supervisors from a total of six manufacturing organizations in Sabah. Measures of trainees' attitudes – self-efficacy, expectancy, job involvement, organizational commitment – and perception of support – job support, managerial and supervisory support, and organizational support are taken before the training. Training outcomes are measured in terms of trainees' reactions to the training, the extent of learning, and the attempt to apply the trained skills at work. Multiple regression analysis is conducted to determine how the above factors affected the training outcomes.

INTRODUCTION

Training could be a costly investment with little assurance of returns. In early 1980's, Georgenson (1982) suggested that probably only 10% of the US$100 billion spent on training and development in USA led to positive transfer. In their study, Baumgartel, Reynolds, and Pathan (1984) found that less than half of their subjects reported significant attempt to transfer training to job environment after training. Marx (1986) suggested that transfer failure might be as high as 90%. In the similar note, Broad and Newstrom (1992) suggested that more than 80% of investment in training is ultimately wasted. Positive returns are not guaranteed for training investment without proper understanding of the training transfer process. Gist and Stevens (1998) proposed that two outcomes contribute to improved returns on training expenditures:

- the maintenance of skilled performance over time, and
- the transfer of skilled performance to related tasks and alternative contexts.

Earlier studies on training effectiveness and transfer dwelt a lot on issues of training designs and conditions. Wexley and Baldwin (1986) described some traditional transfer strategies – conducting training in such a way to:

- facilitate learning of not just applicable skills, but also general rules and theoretical principles underlying the training contents – teaching underlying principles; and
- facilitate use of newly acquired skills in a different work environment – learning underlying principles.

Towards the end of the 1980's, researchers began to show interest in the study of factors besides those related to training designs and conditions. Noe (1986) called for more attention for attitudinal and environmental factors that may affect training transfer. Campbell (1988) stressed that individual and situational variables could all have impact on the ultimate effectiveness of the training program. Baldwin and Ford (1988) acknowledged the significance of trainee characteristics and work environment on training transfer. Foxon (1993) reviewed more than 30 articles to identify 128 factors – organizational climate factors accounted for 42% of all the factors, individual learner characteristics accounted for 22% (motivation alone accounted for 13%), and training design and training delivery factors made up the rest – that inhibit training transfer. . This indicates the significant attention given to the study of attitudinal and environmental factors affecting transfer of training in recent years.

ATTITUDINAL INFLUENCES ON TRAINING OUTCOMES

Besides instructional effectiveness, training contents, and other training design factors, effectiveness of training programs can be influenced directly or indirectly by the attitudinal affinity of the trainees (Baldwin & Ford, 1988; Campbell, 1988; Foxon, 1993; Noe, 1986).

Self-Efficacy

Noe (1986) acknowledged that self-efficacy is an important factor contributing to trainees' motivation to learn in a training experience. Empirical evidence of its contribution to trainees' motivation, and their application and maintenance of trained skills had been found (Gist, Stevens, & Bavetta, 1991; Tracey, Hinkin, Tannenbaum, & Mathieu, 2001). Trainees who are more certain about their ability to cope with the training experience are more likely to learn from it, and transfer the skills learned to their daily work.

Expectancy

Expectancy is the perception that a certain effort will result in outcomes of a particular form. Vroom's (1964) Expectancy Theory suggests that individuals are more motivated if they develop positive expectation of outcomes that are desirable to them. The stronger one's perception that the expected outcomes will follow the effort, the more likely it is for him or her to work hard towards it. Effort-performance and performance-reward expectancies drive individuals in their decisions to take certain courses of action to improve work effectiveness, job behaviors and performance (Arvey, 1973; Hackman & Porter, 1968; Lawler & Suttle, 1973).

In the training context, trainees with stronger expectancies are expected to be more motivated to learn than those with weaker expectancies (Elangovan & Karakowsky, 1999; Noe, 1986; Noe & Schmidt. 1986). This would eventually affect trainees' initiatives and efforts to learn in a training program (Pritchard & Sanders, 1972).

Desirable incentives are considered to be instrumental in influencing one's expectancies and thus the subsequent performances. In some studies, it was observed that subjects were able to distinguish between intrinsic and extrinsic incentives, and that expectancy for intrinsic incentives appeared to have stronger effect on motivation than expectancy for extrinsic incentives (Facteau, Dobbins, Russell, Ladd, & Kudisch, 1995; Lawler & Suttle, 1973).

Job Involvement

Lodhal and Kejner (1965) defined job involvement as "…the degree to which a person's work performance affects his self-esteem" (p.25). It is acknowledged as a factor likely to directly or indirectly influence training outcome and transfer (Cheng & Ho, 2001b; Elangovan & Karakowsky, 1999; Noe, 1986; Noe & Schmitt, 1986). Job involvement was found to have significant influence over learning, and that highly job-involved trainees are likely to acquire more knowledge as a result of participation in training than those who are less job-involved (Noe & Schmitt, 1986). Job involvement was also found to have positive influence over pre-training self-efficacy, which then influences pre-training motivation, and subsequently training reactions and learning outcomes (Tracey et al., 2001).

Organizational Commitment

Organizational commitment had been defined as "…the relative strength of an individual's identification and involvement in a particular organization" (Mowday, Steers, & Porter, 1979, p.226). This definition implies that individuals in an organization with higher level of commitment to the organization are more likely to put in efforts to add value to the organization. It follows that those who are more committed to their organization may devote more efforts to master training contents in training experiences designated by the organization and to apply learned knowledge and skills to the job, believing that such efforts would enhance the effectiveness of the organization. Empirical evidence for such relationship was found in several studies (Cheng & Ho, 2001b; Facteau et al., 1995; Tracey et al., 2001).

TRAINEES' PERCEPTION OF SUPPORT

Apart from trainees' attitudes, their perception of support at work may affect training outcomes as well. Noe (1986) proposed that environmental favorability – in terms of both task constraints and social influences – might affect trainee's motivation to learn and motivation to transfer. One of the categories of training input factors in Baldwin and Ford's (1988) model – besides trainee characteristics and training design – is work environment. Trainees who return to their work after a training experience are more likely to be able to apply what they have learned if they have a supportive work environment. Trainees who perceived their work environment as supportive may also be more willing to learn in training and apply the learned skills on the job after that.

In their study, Tracey, Hinkin, Tannenbaum, and Mathieu (2001) measured work environment in three dimensions covering both the task and social contexts:

- Managerial support: supervisor's relationship with subordinates and their support for training, etc.;
- Job support: opportunity to apply trained tasks on the job; and
- Organizational support: formal organizational system – appraisal, reward, accountability for training, etc.

They found significant evidence that work environment – as a composite of the three dimensions – contributed to trainees' pre-training self-efficacy, which influenced pre-training motivation and subsequently the training outcome measures.

Job Support

Peters and O'Connor (1980) proposed that situational constraints might hinder desirable work outcomes. At the workplace, trainees who intend to apply trained skills on the job may be hindered from doing do by various job-related constraints. They have listed down eight categories of possible situational constraints that may limit work performance - job-related information, tools and equipment, materials and supplies, budgetary support, required services and help from others, task preparation, time availability, and work environment. In the training context, the extent to which trainees are able to apply trained skills on the job may be affected by the situational constraints experienced at their workplace. Situational constraints perceived by trainees would negatively affect their motivation to learn and the development of their self-efficacy over training (Mathieu, Martineau, & Tannenbaum, 1993; Mathieu, Tannenbaum, & Salas, 1992).

Supervisory Support

It is quite commonly acknowledged that supervisory support may influence trainees' effort to apply trained skills on the job (Baldwin & Ford, 1988; Elangovan & Karakowsky, 1999; Ford & Weissbein, 1997). Positive supervisory behavior may influence perception of support by trainees and thus affect their intention to transfer trained skills. Ford, Quinones, Sego, and Sorra (1992) found that supervisor's attitudes as perceived by trainees have influence over the degree to which trained tasks were performed at work. Foxon (1997) observed that both anticipated management support – trainee's anticipation of management support just after a training experience – and reported management support – degree of management support reported by trainees three months after returning to work – have impact on motivation to transfer and measures of training transfer. Van der Klink and Streumer (2002) made similar observation in their study – management support perceived by trainees appeared to be a significant predictor of behavior transfer.

Organizational Support

Eisenberger, Huntington, Hutchison, and Sowa (1986) suggested that individuals tend to form "…global beliefs concerning the extent to which organization values their contributions and cares about their well being" (p.501). It is likely that trainees' perception of organizational support may influence their motivation to learn and to transfer learned skills. Tracey, Tannenbaum, and Kavanagh (1995) found that organizational culture for continuous improvement has significant impact on post-training behavior. Organizational support was included as one of the dimensions of work environment in the study by Tracey and others (2001), and they found that work environment contributed positively to pre-training self-efficacy.

TRAINING OUTCOMES

Research efforts in relations to training evaluation often make references to Kirkpatrick's (1967, 1987, 1994) model of the levels of training outcomes. For the purpose of training evaluation, Kirkpatrick proposed four criteria:

- Reactions : trainee's "liking of" and "feelings for" a training program;
- Learning : principles, facts, and techniques understood and "absorbed" by trainees;
- Behavior : the application of learned principles and techniques on the job, resulting in a change in job behavior; and
- Results : overall performance improvement demonstrated by trainees, contributing to organizational results.

Over the years, researchers had referred to this model for training evaluation studies. In recent years, the hierarchical structure of Kirkpatrick's model had received quite some criticism. Some researchers reviewed large number of articles on training evaluation to find little evidence of interrelationship between the four criteria (Alliger & Janak, 1989; Alliger, Tannenbaum, Bennett, Traver, & Shotland, 1997). Kraiger, Ford, and Salas (1993) criticized Kirkpatrick's model for its:

- Lack of clarity regarding what specific changes to be expected as functions of trainee learning; and
- Difficulty in identifying what assessment techniques is appropriate.

Many shared the feelings that training outcomes should be measured in more operationalized forms. For instance, training reactions have been recommended to be measured in various sublevels (Alliger et al, 1997):

- Affective reactions : liking of and feelings for the training experience; and
- Utility reactions : perceived relevance, utility value, or usefulness of training for subsequent job performance.

Some proposed that learning outcomes should be measured more comprehensively, covering the cognitive, skill-based, and affective domains and their various sublevels (Gist & Stevens, 1998; Kraiger et al., 1993).

Another aspect of training outcomes to take note is training transfer – the attempt to apply trained skills on the job after training. In this context, objective and criterion measures of behavioral performance were often recommended against self-reported measures (Baldwin & Ford, 1988; Cheng & Ho, 2001a; Ford & Weissbein, 1997). This is attempted empirically by researchers through comparison of pre-training and post-training work samples (Mathieu et al., 1992), organizational appraisal exercise (Orpen, 1999), and practical or simulated sessions (Gist & Stevens, 1998; Gist et al., 1991; Mathieu et al., 1993). Baldwin and Ford (1988) had stressed the importance of establishing trainees' baseline of skill/knowledge/behavior before entering the training experience, so that the behavior change resulted from the training can be reasonably deduced.

THEORETICAL FRAMEWORK

The purpose of this study is to determine how trainees' attitudes and perception of support affect training outcomes. Subjects are 81 trainees in a training course on "5S Housekeeping Practices for Industrial Operators".

Training outcomes are considered in terms of training reactions, learning, and training transfer in this study. Training reactions are measured in terms of :

- Affective reactions: trainees' feelings for the training experience; and
- Utility reactions: trainees' perception of how relevant the training contents are to be applied at work.

Learning is considered in terms of gain in declarative knowledge and application-based knowledge as a result of the training course. Declarative knowledge is the concepts and facts related to the course contents. Application-based knowledge is the cognitive ability to apply relevant principles to specific work situations. Training transfer is observed as the behavioral change resulted from the training course. The attitudinal factors considered in this study are self-efficacy, expectancy, job involvement, and organizational commitment; and the support factors in consideration are job support, supervisory support, and organizational support respectively.

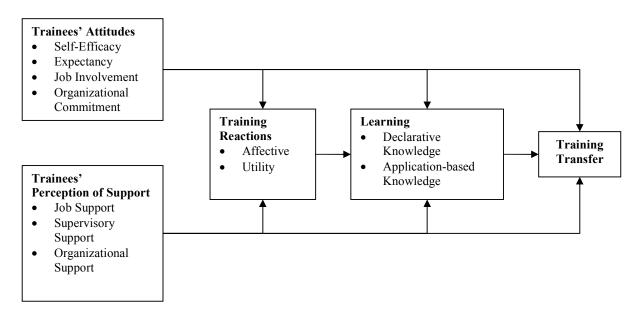
The theoretical framework of this study is built upon the premises that trainees' attitudes and perception of support would affect training outcomes – reactions, learning, and transfer; and that trainees' training reactions would affect learning, and subsequently training transfer. These relationships are illustrated as follows:


Figure 1: Theoretical Framework of the Study

RESEARCH HYPOTHESES

Based on the theoretical framework of the study, trainees' attitudes and perception of support are expected to affect training outcomes. The related hypotheses are:

H1: *Trainees' attitudes – self-efficacy, expectancy, job involvement, and organizational commitment –and perception of support – job support, supervisory support, and organizational support – will significantly affect their affective and utility reactions to the training course.*

H2: *Trainees' attitudes – self-efficacy, expectancy, job involvement, and organizational commitment –and perception of support – job support, supervisory support, and organizational support – will significantly affect the gain in their declarative and application-based knowledge.*

H3: *Trainees' attitudes – self-efficacy, expectancy, job involvement, and organizational commitment –and perception of support – job support, supervisory support, and organizational support – will significantly affect the level of training transfer.*

It is also expected that trainees' reactions to training would affect their learning, and subsequently training transfer:

H4: *Trainees' affective and utility reactions to the training course will affect the gain in their declarative and application-based knowledge.*

H5: *Trainees' affective and utility reactions to the training course will affect their level of training transfer.*

H6: *Trainees' gain in declarative and application-based knowledge will affect their level of training transfer.*

INSTRUMENTS

Several instruments are used for data collection in this study. Trainees' attitudes and perception of support are measured by the Trainees' Entry Condition Survey (TECS). Training reactions are measured by the Training Reactions Survey (TRS). Pretest and posttest scores are used to determine learning. Training transfer is represented by the difference in scores recorded using the 5S Behavior Checklist before and after the course.

Trainees' Entry Conditions Survey

TECS in its final form contains 30 items to measure trainees' self-efficacy, expectancy, job involvement, organizational commitment, job support, supervisory support, and organizational support. The items are presented in 7-point Likert scale, requiring subjects to indicate how agreeable they are to the statement of each item.

Development of TECS

The scales to measure self-efficacy, job involvement, organizational commitment, and organizational support are adopted from previous studies. Items to measure self-efficacy were selected from the 17 items in the General Self-Efficacy Scale developed by Sherer, Maddux, Mercandante, Prentice-Dunn, Jacobs, and Rogers (1982), with Cronbach's alpha coefficient determined to be .86. Items to measure job involvement were taken from the 20 items developed and validated by Lodhal and Kejner (1965) – split-half reliability ranging from .56 to .80. Organizational commitment is measured using items developed by Mowday, Steers, and Porter (1979) , of which Cronbach's α was found to range from .82 to .93, with relatively high test-retest reliability (r = .53, .63, and .75) over two-, three-, and four-months period. Items to measure perceived organizational support were among the 16 items developed by Eisenberger, Huntington, Hutchison, and Sowa (1986), yielding Cronbach α = .93 in the process of validation.

It is necessary to develop items for measuring expectancy specifically related to a training experience. To develop these items, a list of expected outcomes can be obtained from some of the subjects qualitatively as some researchers did (Hackman & Porter, 1968; Pritchard & Sanders, 1972). In this study, 15 employees from two organizations in Kota Kinabalu were gathered in three discussion groups – about five in a group. Brainstorming with these subjects yielded several indicators of possible trainees' expectancy. As some studies had pointed out, expectancy for intrinsic incentives may have stronger effect on motivation that expectancy for extrinsic incentives (Facteau et al., 1995; Lawler & Suttle, 1973), so items developed to measure expectancy in this study focused more on intrinsic incentives. Sixteen items were developed for TECS to measure expectancy based on the information gathered.

Reviewed studies form the basis for the development of items measuring job support and supervisory support. The eight categories of task-related resources proposed by Peters and O'Connor (1980) were used to develop 16

items to measure trainees' perception of job support. The points presented in Foxon's (1997) list of supportive/non-supportive behaviors of managers were used to develop 16 items to measure trainees' perceived supervisory support. This made the total number of items in the TECS 116 items.

Validation of TECS

A total of 116 items measuring trainees' attitudes and perception of support was administered to 95 employees in six organizations in Kota Kinabalu for pilot test.

Multicollinearity is a possible threat in this study as it involved quite a number of independent variables, as seen in some similar studies (Cheng & Ho, 2001b; Facteau et al., 1995). Some precautionary steps need to be taken to prevent such complication. Thus, factor analysis was conducted on the data collected to:
- Identify items with high factor loading for each factor; and
- Eliminate items with high factor loading for more than one factor as practiced by some researchers (Shore & Wayne, 1993).

The 30 items finally selected include four items in each subscale to measure self-efficacy, job involvement, organizational commitment, perceived job support, and perceived organizational support, and five items for each subscale measuring expectancy and perceived supervisory support. The Conbach's alpha value of the subscales ranged from .6506 (job involvement) to .8941 (perceived supervisory support). A number of sample items in TECS are shown in Table 1.

Table 1: Sample Items in Trainees' Entry Conditions Survey

Factor	Sample Item
Self-Efficacy	I give up on things before completing them.
Expectancy	I become more confident with my job abilities if I go through training.
Job Involvement	Most things in life are more important than work.
Organizational Commitment	I am proud to tell others that I am part of my organization.
Job Support	I can easily get information about how to do my job in my organization.
Supervisory Support	My supervisor is often interested in what I have learned from training programs.
Organizational Support	My organization fails to appreciate any extra effort from me.

Training Reactions Survey

TRS is used to measure trainees' affective and utility reactions to the 5S training course. Twelve items had been initially developed for this purpose – six items for affective reactions, and another six for utility reactions. These items are pilot tested on 59 postgraduate students attending distance learning programs in Kota Kinabalu. Factor analysis was carried out to identify eight items – four for each domain of training reactions – to be included in the final form of the instrument. Examples of these items are:
- I find the course really interesting. (Affective reactions)
- The course contents and activities are relevant to my work. (Utility reactions)

The scales of four items each for trainees' affective reactions and utility reactions yielded Cronbach's alpha values of .8729 and .8264 respectively in the pilot test. Like TECS, the selected items are included in the TRS in 7-point Likert scale format.

Pretest and Posttest

The pretest and posttest are parallel tests developed based on the contents of the 5S training course. Each test contained 25 questions in two sections testing trainees' knowledge on training contents covered in the 5S training course. Section A contained 15 multiple-choice items testing trainees' declarative knowledge, and Section B contained 10 items testing trainees' application-based knowledge. Questions in Section A tests trainees' recall and comprehension of the course contents, for example:

The 5S system is beneficial to industrial operations because it :
- reduce cost of production.
- produce skillful workers.
- cultivate team spirit among workers.
- improve operational effectiveness.

Questions in Section B contained descriptions of practical work situations, requiring subjects to respond by selecting the appropriate actions from a list of alternatives, for example:

In-process inventory in Section 4 often piles up in an area near to machine Alpha-1 while waiting to be processed. Sami feels disturbed about this situation because the pile of materials may cause problems in the workplace. What are some steps to be taken so that orderliness in the workplace can be maintained?

- Clearly label the materials.
- Paint lines and box around the area when the materials are often left.
- Cover the materials with lining or plastic.
- Ensure that the materials are clear off the walkway and paint divider lines to show the path clearly.

5S Behavior Checklist

This study adopts the recommendations to obtain objective and criterion measures of behavioral performance against self-reported measures (Baldwin & Ford, 1988; Cheng & Ho, 2001a; Ford & Weissbein, 1997). The trainees' related behaviors are measured using a checklist developed for the purpose. The 5S Behavior Checklist contained 20 items to measure specific trainee behaviors in three specific areas – organization (*Seiri*), orderliness (*Seiton*), and cleanliness (*Seiso*). Trainees' behaviors are observed through indicators such as whether there are visible indications of

- needed and unneeded items,
- storage places for items, and
- cleanliness procedures and actions at their workplace.

The items in the checklist were modified from the sample checklists presented by Hirano (1990/1995). A sample item is as follows:

Storage of items (what goes where and in what amount)
> 1-Impossible to tell
> 2-Possible (but not easy) to tell
> 3-There are general storage signs
> 4-Anyone can see at a glance

METHOD

This study adopts a pretest-posttest quasi-experimental design involving a group of trainees in a 5S training course. These trainees are operators and supervisors of seven manufacturing organizations situated in the West Coast of the state of Sabah in Malaysia.

Subjects

The subjects of this study are 81 trainees for a 5S training course. They are operators and supervisors in seven manufacturing organizations in Sabah. The organizations of the subjects were invited to participate in this study by sending their operators and operations supervisors for the 5S training course developed for this purpose. They were selected by the management of their respective organizations based on the organization's operational needs and conditions – whether the subject matter is of interest and technical benefit to the organization in general, whether it is possible to release workers from daily operations for training, and so on. So, trainees from the same organization either took turns or were relieved from their normal work shift to join the training course. This manner of selection appears to be a rather common practice for training among Malaysian organizations as observed in surveys conducted by Malaysian Institute of Management (1996) and Wong (2000).

5S Training Course

The 5S training course is developed and conducted by the researcher, who is a training consultant having experience in implementing and auditing quality systems. The course is conducted in Bahasa Malaysia, the Malaysian national language commonly used by industrial operational workers in Sabah. To accommodate operational needs of the participating organizations in Kota Kinabalu, the course was conducted in two alternative sessions in Sabah Skills and Technology Centre in Sepangar Bay, Kota Kinabalu. One other session is conducted on-site for one participating organization having a total of 26 trainees for the course. The course contents and activities for all three sessions are similar to ensure that the training design and condition are controlled.

Attitudes and Learning

Measure of trainees' attitudes and perception of support is taken by administering the TECS before each training session begin, followed by the pretest. Immediately after each course, the posttest is administered and then the TRS. The Bahasa Malaysia version of the instruments is used.

Training Transfer Measures

As an objective measure of training transfer, behavioral measures were taken at the trainees' workplace before and after the training course. Within one week before the training course, the researcher visited the trainees' workplace and made a record of the pre-training behaviors based on the 5S Behavior Checklist. This serves as the baseline behavior of the trainees before the training course (O1). Two weeks after the training, the researcher visited the trainees again to make another behavioral measure (O2). The difference between the behavioral performance scores at O1 and O2 is considered as the training transfer sustained by trainees as a result of the training course.

RESULTS

To test the hypotheses of this study, correlation and regression analysis is applied. Pearson correlations between the factors in consideration are presented in Table 2. Based on this correlation matrix, the independent variables with higher correlation with the dependent variable concerned are entered first for regression analysis. The results of multiple regression analysis using this approach are presented in Table 3.

Statistical Power Analysis – A Priori, Post Hoc, and Compromised Approaches

The sample size of 81 has statistical influence on the power of the F test in multiple regression analysis involving at least seven predictors in this study. By a priori approach, it can be determined by statistical power analysis that to conduct F test in multiple regression analysis involving seven predictors, a sample size of at least 103 is required to sustain the power of the test at 80% while applying level of significance, $\alpha = 5\%$. Post hoc approach of such analysis revealed that, by having a sample size of only 81, the power of the test is reduced to about 67% if α is to be maintained at 5%. This means that, when testing F value for seven predictors of one certain variable with a sample size of 81, the probability of rejecting the null hypothesis when it is false falls from 80% to only about 67% in order to maintain a 5% margin of error so as not to reject the null hypothesis when it is true.

Erdfelder, Faul, and Buchner (1996) offered an alternative to this threat. They contended that there are often practical constraints that make it difficult for researchers to gather a large number of subjects for their studies. They proposed a compromised approach in statistical power analysis. Taking the ratio of β/α to be 1, they were able to determine the value of α and β that is applicable for the realistic sample size in consideration. For this purpose, they initiated the effort to develop a software for statistical power analysis bearing such features – G*Power (Erdfelder et al., 1996). G*Power is a DOS-based freeware for statistical power analysis, supporting three approaches of power analysis – a priori, post hoc, and compromise. It allows users to carry out power analysis by any of the three approaches based on parameters entered for various types of statistical tests. This

software is used to determine the value of α and β in the compromised situation of having a sample size of only 81 in this study.

It is important to note that when the compromised approach is taken, the risk of committed α error – rejecting the null hypothesis when it is true – in hypothesis testing will inevitably increase, although the power of the test – the probability of rejecting the null hypothesis when it is false – is maintained at a reasonably acceptable level of 80% and above. For example, when testing seven predictors in multiple regression with a sample size of only 81, compromised analysis yielded the level of significance, α to be .1546 (about 15%) for the power of the test, $1 - β$, to be .8454 (about 85%).

Post Hoc Analysis

To test the hypotheses in this study, multiple regression analysis is performed. Testing for hypothesis H1, it is found that only expectancy contributed significantly to the variance in affective reactions ($\Delta R^2 = .250$, $p < .01$), while expectancy ($\Delta R^2 = .140$, $p < .01$) and job involvement ($\Delta R^2 = .063$, $p < .05$) are found to have significantly contributed to the variance in utility reactions. Apparently, trainees' expectancy of favorable outcomes from the training course has significant impact on their affective and utility reactions for the training course; and the degree to which they are involved in their job seemed to be an important predictor of their utility reactions.

To determine the effects of trainees' attitudes, their perception of support, and training reactions on learning, the seven related factors and training reactions measures – affective and utility – are entered one by one as independent variables. The analysis revealed that only self-efficacy contributed significantly to the variance of trainees' gain in declarative knowledge ($\Delta R^2 = .058$, $p < .05$) and only job involvement contributed significantly to trainees' gain in application-based knowledge ($\Delta R^2 = .058$, $p < .05$). It is interesting to note that the effects of training reactions measures on learning were insignificant contrary to hypothesis H4.

To determine the effects on training transfer, all related factors were entered hierarchically for regression analysis based on the strength of their correlation with training transfer. Trainees' gain in application-based knowledge was entered first, followed by trainees' gain in declarative knowledge. This is followed by affective reactions and then utility reactions. Trainees' attitudes were entered in two groups. Self-efficacy and expectancy was entered first as they are considered personality-related factors. Job involvement and organizational commitment was entered next as factors related to job attitudes. Finally, all the factors related to trainees' perception of support – job support, supervisory support, and organizational support – were entered as one group. In total, seven predictors were entered as independent variables. There is insufficient evidence to support hypotheses H3, H5 and H6, which claim that these factors will have significant effect on training transfer.

In conclusion, the multiple regression analysis carried out by Post Hoc approach – with a sample size of 81 subjects, taking α to be .05, and power of F test to be .6672 (testing seven predictors) and .6061 (testing nine predictors) – revealed that:
- Trainees' expectancy has significant effect on their affective reactions;
- Trainees' expectancy and job involvement have significant effect on their utility reactions;
- Trainees' self-efficacy has significant effect on their gain in declarative knowledge; and
- Trainees' job involvement has significant effect on their gain in application-based knowledge.

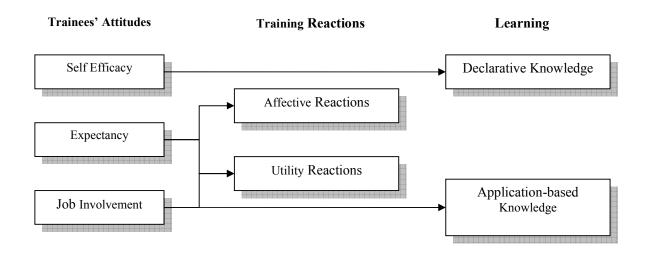
These relationships are illustrated in Figure 2.


Figure 2: Model by Post Hoc Analysis

In this Post Hoc Model, it is observed that trainees' perception of support has insignificant effect on all the training outcome measures.

Compromised Analysis

Facing the constraint of having a limited sample size, the compromised approach in statistical analysis as recommended by Erdfleder, Faul, and Buchner (1996) is also carried out. As there is still much to learn about how trainees' characteristics and work environment would affect training effectiveness, some researchers pointed out the need to develop, test, and refine related theoretical models (Baldwin & Ford, 1988; Cheng & Ho, 2001a). Conducting the compromised analysis may contribute in the efforts to form a more comprehensive theoretical model on the subject of the study although the risk of errors in making conclusion about significant effects is higher than taking the Post Hoc approach.

In consideration of training reactions, it is observed that trainees' expectancy (ΔR^2 = .250, p < .1546, predictors = 7), self-efficacy (ΔR^2 = .021, p < .1546, predictors = 7), and perceived organizational support (ΔR^2 = .020, p < .1546, predictors = 7) contributed significantly to their affective reactions to the training course. In relations to their utility reactions to the training course, it is noted that expectancy (ΔR^2 = .140, p < .1546, predictors = 7), job involvement (ΔR^2 = .063, p < .1546, predictors = 7), and self-efficacy (ΔR^2 = .022, p < .1546, predictors = 7) are the significant predictors.

Regressing trainees' gain in declarative knowledge against the related factors, apart from the finding that self-efficacy (ΔR^2 = .058, p < .1745, predictors = 9) has significant contribution, trainees' perceived job support is also observed to be a significant predictor (ΔR^2 = .029, p < .1745, predictors = 9). Even with compromised analysis, the training reactions measures are still found to be insignificant in terms of contribution to the variance in trainees' gain in declarative knowledge. For trainees' gain in application-based knowledge, job involvement (ΔR^2 = .058, p < .1745, predictors = 9) and self-efficacy (ΔR^2 = .025, p < .1745, predictors = 9) are found to be significant predictors.

Compromised analysis revealed that trainees' attitudes and perception of support made insignificant contribution to the variance in training transfer. However, trainees' gain in application-based knowledge contributed – although little – significantly to the variance in training transfer (ΔR^2 = .026, p < .1546, predictors = 7). This appears to be consistent with the results in correlation analysis. None of the factors in consideration appeared to have significant Pearson's correlation with training transfer. However, the Spearman's ρ value between trainees' gain in application-based knowledge and training transfer is found to be significant (ρ = .222, p < .05). This indicates the possibility of having a large number of outriders in the relationship.

By applying compromised analysis, it is found that:
- Trainees' expectancy, self-efficacy, and perceived organizational support have significant effect on their affective reactions;
- Trainees' expectancy, job involvement, and self-efficacy have significant effect on their utility reactions;
- Trainees' self-efficacy and perceived job support have significant effect on their gain in declarative knowledge;

- Trainees' job involvement and self-efficacy have significant effect on their gain in application-based knowledge; and
- Trainees' gain in application-based knowledge has significant effect on the level of their training transfer.

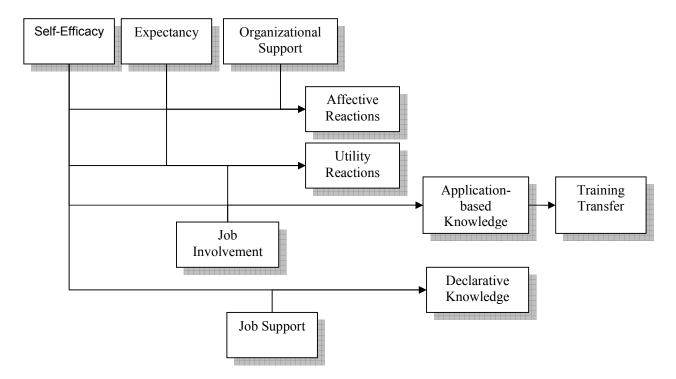
These findings are illustrated in Figure 3.


Figure 3: Model by Compromised Analysis

The Compromised Model revealed some interesting findings. Whereas trainees' self-efficacy is only found to contribute significantly to their gain in declarative knowledge in the Post Hoc Model, it is found to have significant effect on all measures of training reactions and learning. As determined in the Post Hoc analysis, trainees' expectancy is found to have significant contribution to training reactions measures, and their job involvement level affects both utility reactions and gain in application-based knowledge.

The effects of trainees' perception of support on training outcomes are found to be insignificant in Post Hoc analysis. By compromised analysis, it is found that trainees' perception of organizational support has significant effect on affective reactions, and their perception of job support contributed to their gain in declarative knowledge. There is no significant effect found for training transfer by Post Hoc analysis. In the Compromised Model, however, it is found that trainees' application-based knowledge contributed significantly to their training transfer.

DISCUSSION

The items to measure training-related expectancy in this study focused on intrinsic incentives that may have resulted from training experiences – such as having more confidence, improved work effectiveness, respect from peers, and so on – suggested to have stronger effect on trainees' motivation than extrinsic incentives (Facteau et al, 1995; Lawler & Suttle, 1973). The results of this study appeared to have confirmed such notion, as expectancy measured on this basis has been found to have significant effect on – at least – the training reactions measures. It contributed to 25% of the variance in affective reactions and 14% to the variance in utility reactions. This indicates that the strength of trainees' expectation of certain desirable outcomes from the training course may positively enhance their possible reactions towards the training course. Managers, employers, or trainers should consider conducting pre-training briefing exercises to help trainees' prepare mentally for training experiences, so that their training-related expectancy can be strengthened and thus more likely to yield positive reactions to the training.

Job involvement has been found to have moderately significant effects on trainees' utility reactions (6.3%) and gain in application-based knowledge (5.8%). It is reasonable to see that trainees' who are more involved in their

job are more likely to see relevance in the course contents with their work. It is interesting to note, however, that trainees' job involvement is actually negatively correlated with their gain in application-based knowledge (Table 2) ($r = -.241$, p < .05). Trainees' ego involvement in their job seemed to have impeded the extent of their application of the newly acquired knowledge and skills in work situations conceptually. Trainees who are more involved in their job knows their work well, and are likely to have developed habits, ideas, and opinions about how to handle certain work situations as a result of their work experience. These may hinder them from changing their mindset to apply newly acquired knowledge and skills in the work situations described in the pretest and posttest. Thus, it may be necessary for managers, employers, or trainers, to take steps help the trainees to apply the newly acquired knowledge and skills - provide more practical examples, develop action plans together with the trainees, and so on.

Self-efficacy is observed to be a significant predictor for trainees' gain in declarative knowledge in the Post Hoc Model (Figure 2). In the Compromised Model (Figure 3), it is found that trainees' self-efficacy also significantly affect training reactions and gain in application-based knowledge. In terms of learning, it appeared to have positive effects on trainees' gain in declarative and application-based knowledge (5.8%, $r = .241$ and 2.5%, $r = .096$). On the other hand, self-efficacy has negative correlation with training reactions measures, contributing 2.1% to the variance in affective reactions ($r = -.110$) and 2.2% to the variance in utility reactions ($r = -.009$). Trainees' confidence of their competence appeared to have enhanced their learning in a training experience. However, there seemed to be a tendency for trainees with high level of self-efficacy to develop slightly negative feelings towards the training course, perhaps due to the fact that the 5S training course covered rather basic contents and so presents less challenge and appeal to them.

Trainees' perception of support is found to be insignificant in its effect to training outcomes in Post Hoc analysis. However, by the Compromised analysis, the effects of trainees' perception of organizational support and job support are found to be significant. Trainees' perceived organizational support is found to have moderately positive contribution to their affective reactions (2%, $r = .093$); and their perceived job support has positive effect on their gain in declarative knowledge (2.9%, $r = .067$). The trainees' perception about how seriously the organization takes care of their well being may affect their affective reactions to training, and their perception of whether they are being supported well at their job would affect their conceptual learning. It seemed that if trainees are positive that their organization genuinely care about their well being, they would be more likely to develop positive feelings about training experiences, perhaps accepting these as a part of how the organization contribute to their development. They would also be more successful in learning the facts and concepts covered in the training – perhaps more willing to exert efforts and initiatives to learn – if they are positive that they are being adequately supported at work.

Contrary to what was hypothesized in H3, H4, and H5, there is insufficient evidence of significant effect of
- trainees' attitudes and perception of support on the level of their training transfer;
- trainees' reactions to training on their learning; and
- trainees' reactions to training on the level of their training transfer

In both Post Hoc and Compromised analysis. However, in the Compromised Model, it is found that trainees' gain in application-based knowledge has moderate significant contribution to the level of their training transfer (2.6%). This indicates a possible link between trainees' ability to apply acquired knowledge in work situations conceptually and their eventual success or failure in applying the knowledge at work. It is more likely for trainees who are more successful in applying conceptual knowledge in simulated work situations to be able to apply the related knowledge at work. Therefore, managers, employers, or trainers should consider having simulated activities – such as case studies, role-play, hands-on exercise – in training programs so that trainees can apply what they have learned in near-real situations. This would enhance the possibility of transferring the learned skills to the actual work situations.

Despite of efforts to reduce possibility of multicollinearity, significant correlations between the independent variables are still observed. Trainees' organizational commitment is found to have significantly high correlations with expectancy ($r = .578$), job support ($r = .373$), and supervisory support ($r = .498$). Trainees' perception of supervisory support has significantly positive correlations with expectancy ($r = .498$), organizational commitment ($r = .461$), job support ($r = .546$), and job involvement ($r = .277$). The lowest tolerance index for collinearity diagnosis for multiple regression analysis involving all independent variables is registered as .435. Although still acceptable, the fact that possible problem of multicollinearity should be noted nonetheless. Perhaps the number of independent variables to be considered should be reduced in future researches.

It is also noted that significant Pearson's correlation between training transfer and the other variables is not found, but its correlation with trainees' gain in application-based knowledge is found to be significant when considering Spearman's rho. This may be an indication of the presence of large number of outriders in the relationships. Perhaps if the sample size is larger, the tendency and effect of outriders may be reduced.

CONCLUSION

In this study, trainees' attitudes and perception of support is hypothesized to have significant effects on training reactions, learning, and training transfer (H1, H2, H3). It is also hypothesized that training reactions would affect learning and training transfer (H4, H5), and that learning would affect training transfer (H6). The results of the study revealed that

- trainees' self-efficacy have significant effects on training reactions and learning;
- trainees' expectancy has significant effect of training reactions;
- trainees' job involvement has significant effect on utility reactions and gain in application-based knowledge;
- trainees' perceived organizational support has significant effect on affective reactions;
- trainees' perceived job support has significant effect on gain in declarative knowledge; and
- trainees' gain in application-based knowledge has significant effect on their training transfer.

Contrary to H4 and H5, no significant effect on learning is observed from training reactions on learning and training transfer. Also, no significant effect is found from trainees' attitudes and perception of support on training transfer (H3).

ABSTRACT
Despites the importance of FAFH, limited attempt has been made to study the economics of this emerging cultural change. This may be due to underestimation of importance of FAFH, especially when the food sector is mostly studied at aggregate level. The general objective of this study is to analyze FAFH consumption in Malaysia. Specifically, the objective of this research is to analyze the determinants of FAFH demand and examine how socioeconomic factors of consumers have contributed to FAFH. The control variables for the study provided expected coefficients that are significantly different than zero. As the level of development increase, household structure changes simultaneously with income increase that lead to an increase in FAFH expenditure. This study has shown that FAFH has the propensity to increase with an increase in income. FAFH high-income elasticity provides a good indicator for FAFH industry demand.

INTRODUCTION

Food consumption patterns have changed over time as a result of development. Coupled with an increase in income and urbanization, total expenditure on food away from home 'FAFH' has increased rapidly. The rising FAFH demand has stimulated the development of other economic activities especially in the service sector such as franchising, packaging and catering. In line with this development it is inherently important to understand the demand of FAFH.

Despites the importance of FAFH, limited attempt has been made to study the economics of this emerging cultural change. This may be due to underestimation of importance of FAFH, especially when the food sector is mostly studied at aggregate level. The general objective of this study is to analyze FAFH consumption in Malaysia. Specifically, the objective of this research is to analyze the determinants of FAFH demand and examine how socioeconomic factors of consumers have contributed to FAFH. To meet these objectives the paper is organized as following. The next two sections describe the data and sketch a picture of FAFH consumption behavior followed by empirical approach and discussion of the results.

Consumer Expenditure on Food in Malaysia

Changes in lifestyle and demographic affect consumer demand for goods and services. Traditionally, Malaysian households' consists of married couples with a working husband, non-working wife and their children. On the other hand the non-traditional household comprising of working wife households, single parent household and household of multiple adult without live at home child are increasing. An average Malaysians would normally have four daily meals. Not surprising, the largest chunk of expenditure was accounted for by food and drink with a combined expenditure of M$32,971 million in 2000.

The traditional household would have their meals at home and the non-traditional one would have it away from home. In light of the changing structure of the households, the growth in ready meals and pre-packaged foods has pushed up spending on food. Thus families are eating out more either at fast-food restaurants as well as traditional restaurants. Studies shows that change in consumer demand have impacted the structure of the food industry (Goodwin and Brester, 1995; Senauer *et al.*, 1991).

Changing lifestyle resulting in increasing popularity of eating out amongst Malaysians with an evident increase in dining in fine restaurants as well as in cheaper food stalls popularly known as hawkers "*gerai.*" The majority of non traditional household Malaysians consume their breakfast, lunch and dinner at   food stalls, which are often more cost effective than preparing their meals.

There are many factors that may be considered in this study to determine demand for FAFH in Malaysia. Any economic text infers that income is a very important determinant of demand. The income structure of Malaysian is also associated with the various races where the Chinese ethnic is associated with high income. In addition, the Chinese family likes to dine out. Chinese in Malaysia are normally associated with family business activities that require them time to be spent on business rather than home. Therefore demand for FAFH for Chinese would be higher. FAFH is also connected with the level of development where income is high in more developed region. The level of development in Malaysia differs from one State to another. The Peninsular Malaysia is more developed than Sarawak and Sabah. Thus most of the European and American food chains are concentrated at major cities in the Peninsular. European and American foods are popular, through restaurant chains such as Kentucky Fried Chicken, McDonald's and Shakey's Pizza. Analyzing the income elasticity of demand of FAFH is important in understanding future size of the service industry.

FAFH is also popular among students and office workers (white collar profession). These stalls normally charge lower price as they cater to customers with lower income. These are traditionally roadside stalls though now typically gather together in formal areas or even modern style food courts. Most sell traditional Malaysian dishes for low prices.

METHODOLOGY

To test hypotheses how FAFH demand is affected by socioeconomic factors, a data set on information of household namely the Household Expenditure Survey, 1999 was used. The demand model is constructed using (Becker, 1965).[1] The dependent variable constitutes the value in (RM) spent by the household and the independent variables constitute dummy variables representing education, profession, gender, household head status, races, ages and location,

The Becker's New Household Economics Model s an extension of the demand theory, which deem prices, income, demographics, and time constraints affecting households purchases of items. The salient feature of this model is the inclusion of opportunity cost as an important factor in allocating expenditure of FAFH. In this study the opportunity cost is time spend in term of preparing the food including purchasing the ingredients, and cleaning after meal which determine the household decision as whether to choose eating away from home The demand for FAFH can be estimated by:

$$F_{ih} = F(Z_{ih}, Y_{ih}, Z_{ih}),$$

where F_{ih} is the expenditure on FAFH on the ith individual and hth household,
   Y_h is the hth household's income,
   and Z is a vector of variables including all other control variables

Descriptive statistics for the variables that are used in the modeling of FAFH in Malaysia are summarized in Table 2.

Not all respondents in this study reported FAFH expenditure during the sample study period. Only 96.1 percent of the respondents reported their FAFH expenditures during the survey period, while 3.9 percent of the sample reported that they had made zero expenditures on FAFH. Without taking the zero expenditure sample into consideration would lead to statistical bias. Thus in overcoming this problem, Tobit modeling framework utilizing censored dependent variable is applied.

Using the work Deaton and Irish (1984) and by assuming a linear equation, Tobit formulates   both   latent demand and observed demand as: -

$$Y^* = \beta'X + \varepsilon, \text{ (latent demand)}$$
$$Y^{**} = \max(Y^*, 0) \text{ (observed demand)}.$$

The log likelihood function is being used in Tobit model and is expressed as: -

$$L(\beta,\sigma) = \prod_0 \Phi(1 - \beta'X/\sigma) \prod_+ \varphi[(Y - \beta'X)/\sigma]/\sigma$$

---

[1] This method is also being employed by Ma Hengyun et. al. (2002)

where   Φ the cumulative probability distribution function
ϕ Is the density function of a standard normal random variables, and
σ is the standard deviation of ω.

The subscripts 0 and + mean that summation is performed over the sub-sample in which dependent variable is zero and positive.

Like McCracken and Brandt (1987), the unconditional and conditional expected value of the dependent variable, Y_i, in the Tobit analysis can be written as:

$$E(Y_i \mid X_i) = F\left(\frac{\beta' X_i}{\sigma}\right)(\beta' X_i) + \sigma f\left(\frac{\beta' X_i}{\sigma}\right) \text{ and}$$

$$E(Y_i^* \mid X_i) = E(Y_i \mid X_i, Y_i) > 0) = (\beta \beta X_i) + \sigma f\left(\frac{\beta' X_i}{\sigma}\right) / F\left(\frac{\beta' X_i}{\sigma}\right)$$

where   F (.) is cumulative normal distribution function.
f(.) is the standard normal density, respectively.

Hence, total elasticity of expected value, Y_i, for the kth variable can be decomposed as:

$$E_i = \frac{\partial F\left(\frac{\beta' X_i}{\sigma}\right)}{\partial X_i} \frac{X_i}{F\left(\frac{\beta' X_i}{\sigma}\right)} + \frac{\partial F(Y_i^* \mid X_i)}{\partial X_i} \frac{X_i}{E(Y_i^* \mid X_i)}$$

The first part of the equation representing elasticity of the probability of consumption and the second part is the elasticity of expected consumption of presently consuming individuals.

RESULT AND DISCUSSION

Table 3 depicts the determinants of FAFH consumption, where the R-square of an OLS   (excluding zero value observation) is 0.29, which is an acceptable level. The control variables also provide expected coefficients that are significantly different than zero. Male gender, age of head household groups (less than 20 year, 21-35 year, and 36-50 year) and education level of household (SRP, SPM, STPM/Diploma and Degree level) show that these groups of individuals spend more on meals away from home than others. FAFH demand is higher among Chinese compared to Malay and Indian, professional and white collar workers relative to blue-collar workers. This may be due to blue-collar workers consumer pack lunches from home.

Level of development is positively related to the increase in demand of FAFH. Thus not surprisingly this study shows that the FAFH demand is higher in Peninsular Malaysia compared to Sabah and Sarawak.   In addition FAFH demand is also higher at urban areas compared to rural areas.   In sum, well off, and urban area individuals are the consumer group that is the one most likely to be eating out than rural area. The result also shows that negative and significant signs on the coefficients of number of household members less than 12 years old, which indicate that children consume less away from home compared to adult.

The result also suggests significant relationship between income levels and demand for FAFH. The coefficient of the household income variable in the total expenditure equation is positive and highly significant.

Rise in demand of FAFH has been driven by rising incomes (Table 4) the income elasticity shows that on average, for each 1 percent rise in income, expenditure on FAFH rose by 0.753 percent. However, income elasticity increased with respect to increase in income, suggesting that FAFH demand is higher among the wealthier (1.747) compared to lower level income (0.469 for income per capita less RM1000).   The disaggregating of the total elasticity suggests that it is the enlargement of market participation that is contributing the increasing FAFH demand (about 0.452 of 0.753).

Age structure also influences income elasticity of FAFH. As shown in Table 4 income elasticity increased from lower to middle age groups and declined at the older age group (more than 50 years old). This in line with the declining of income and activities as the retirement age for Malaysian is 55. Thus middle age consumers are the consumer group that is more likely to be eating out due to the rapid rise in their income.

CONCLUSION

In this paper, we have shown the determinants of demand for FAFH. We have shown the socio economic factors that determine demand for FAFH. As the level of development increase, household structure changes simultaneously with income increase that lead to an increase in FAFH expenditure. This study has shown that FAFH has the propensity to increase with an increase in income.

FAFH high-income elasticity provides a good indicator for FAFH industry demand. FAFH industry can expect high growth as Malaysia is set to become a developed nation by 2020. Consumers would have less time to prepare their food; instead they will opt to eat away from home.

Fiscal Sustainability in Three Crisis Affected ASEAN Countries

Evan Lau and Ahmad Zubaidi Baharumshah
Department of Economics

43400 UPM Serdang, Selangor, Malaysia

ABSTRACT

Following the literature, fiscal sustainability criterion is usually adopted to evaluate whether or not fiscal policy is under control. The fiscal policy is sustainable if the government intertemporal budget constraint (GIBC) holds in the present value terms. Conversely, if the budget is out of control, economic polices at both macro and microeconomic levels will quickly become unsupportable and require changes to be made. The main purpose of this paper is to assess empirically the issue of long run fiscal sustainability imbalances in three ASEAN crisis-affected countries (Malaysia, the Philippines and Thailand). The sampling period are divided into two sub-periods of pre (1975:1-1997:2) and post crisis (1975:1-2003:2). The statistical computations indicate that the fiscal stance in Thailand is on sustainable path while Malaysia and the Philippines are seeking for one in the full sampling period. From the policy perspectives, the needs for fiscal consolidation and prudent fiscal policies is essential in these countries for reducing public debt, improving operation of monetary and exchange rate policies, facilitating private sector-led growth in promoting sustainable economic performance. This acts as one of the important ingredients for the ASEAN region to band together towards the economic and monetary cooperation.

INTRODUCTION

The resurgence of interest on the sustainability of the fiscal deficit has arise from two important developments in the global economy: (1) the large fiscal imbalances witnessed in many of Western Europe and the Unites States over the past two decades; and (2) the fiscal discipline demanded from the European Union (EU) member countries for European Monetary Union (EMU) membership by the end of the 1999. They required that the governments runs a budget deficit of no more than 3 percent of national income and that the amount of government borrowing should not 60 percent of national income measured as real GDP. In addition, International organization like the World Bank and the International Monetary Fund (IMF) had developed and regulated wide-ranging plan in assessing and monitoring fiscal sustainability among their member countries (Chalk and Hemming, 2000 and Edwards, 2002).

In principle, an economy will be able to sustain fiscal deficit as long as it can raise the necessary funds by borrowing. Although such a policy is feasible in the short run, the ability of the economy to service its debt by resorting to further borrowing in the long run is likely to be questioned once the deficit become persistent. In this sense, sustainable fiscal policies are those that can be continued indefinitely without any modification. In other words, the fiscal policy is sustainable if the government intertemporal budget constraint (GIBC) holds in the present value terms. Conversely, if the budget is out of control, economic polices at both macro and microeconomic levels will quickly become unsupportable and require changes to be made. If such phenomenon does occur, then the budget imbalances would imply a need for larger and more painful macroeconomic adjustments for the economy. Given the detrimental impact of persistent deficit finance practices on debt accumulation, inflation rates, interest rates and economic growth, evaluating and monitoring the sustainability fiscal policies in the long run is an extremely important task to answer.

There has been a substantial volume of empirical studies focusing on the sustainability of government's fiscal financial strategy. In this context, two different empirical approaches have been used to analyze the sustainability of fiscal polices. The first approach was initiated by Hamilton and Falvin (1986) and was further empirically tested in Kremers (1988), Trehan and Walsh (1988), Wilcox (1989), Smith and Zin (1991), MacDonald (1992), Makrydakis *et al.* (1999), Feve and Henin (2000), Olekalns (2000) and Uctum and Wickens (2000). This line of research tests the univariate stationarity of the debt and/ or deficit. The second approach originated by Hakkio and Rush (1991) in examining the bivariate long run cointegration relationship between government revenue and expenditure (see also empirical evidence by Tanner and Liu, 1994; Liu and Tanner, 1995; Quintos, 1995; Payne, 1997; Papadopoulos and Sidiropoulos, 1999; Martin, 2000; Hatemi-J, 2002). Most of these studies focus on the US and the Western European countries. Only recently, empirical investigations on intertemporal fiscal solvency constraint on the Asian region and the transition economy (eg. Eastern Europe) have becoming increasing available in the literature (see for example, Wu, 1998; Green *et al.*, 2001; Chung, 2002; Cashin *et al.*, 2003).

Following this development, the main purpose of this paper is to provide an in-depth analysis and draw some policy lessons empirically on the issue of long run sustainability of fiscal imbalances in three crisis-affected ASEAN countries namely, Malaysia, the Philippines, and Thailand. These groups of countries lapsed into severe financial crises in 1997. Looking back on the historical data, these countries running imbalances of fiscal position in some of the years while surplus in the other years. Interestingly, after the financial turmoil in 1997, the fiscal position of these countries swung into negative figures (4 percent of GDP). This paper also attempt to answer the question of whether the fiscal imbalances recorded in the post-crisis era are consistent with the sustainability criterion by dividing the quarterly sample period (1975:1-2003:2) into two sub-samples of pre (1975:1-1997:2) and post (1975:1-2003:2) crisis.

To research this problem, we adopted nonstationary econometric time series analysis. This includes the unit root tests and the cointegration techniques. This paper also considers the issue of potential structural break(s) with cointegration by Gregory and Hansen (1996). In order to test the necessary and sufficient condition of sustainable fiscal policy, we used the Stock and Watson (1993) dynamic OLS (DOLS) approach. For this reason, time series data on government expenditure and revenue are examined to establish whether successive government conduct of fiscal policy has been consistent with the existence of the GIBC. In addition, we provide a formal theoretical framework for analyzing the sustainability of fiscal policy based on GIBC framework.

The remainder of the paper is organized as follows. Section 2 discusses the theoretical underpinnings based on GIBC, its association to the long run fiscal policy sustainability and its testable implications. Section 3 outlines the empirical methodology for testing GIBC and a data description. Econometric evaluation of the findings are presented and discussed in Section 4. The main conclusions and policy implications are summarized in Section 5.

GOVERNMENT INTERTEMPORAL BUDGET CONSTRAINT: SUSTAINABILITY CONDITION

To investigate whether the government's intertemporal budget constraint being fulfilled in the long run, let us consider the budget constraint faces by a government at period *t* written as

$$G_t + (1+r_t)B_{t-1} = RR_t + B_t \tag{1}$$

with G_t is the value of government purchase of goods and services and transfer payments, RR_t is the government revenue, B_t is government debt and r_t is the (one period) interest rate. It is worth noting that the variables in Equation (1) can be nominal, real or "deflated" by population or real GDP[1].

The budget constraint in Equation (1) is pertains to only period *t*. Subsequently, there is similar constraint as Equation (1) for periods of *t*+1, *t*+2, *t*+3,…, *t*+n and recursively solving that equation via forward substitutions leads to the following government intertemporal budget constraint of

$$B_0 = \sum_{t=1}^{\infty} \delta_t [RR_t - G_T] + \lim_{n \to \infty} \delta_n B_n \tag{2}$$

where $\delta_t = \prod_{s=1}^{t} \beta_s$ where $\beta_s = 1/(1+i_s)$, and δ_t is the discount factor. Equation (2) shows that the current value of government debt B_0 is equal to the expected present value of all future primary surpluses $\sum_{t=1}^{\infty} \delta_t [RR_t - G_t]$, plus a limiting term that represents the asymptotic expected present value of the government's debt. The crucial element in Equation (2) is the last term *lim* $\delta_n B_n$, where the limit is taken as $n \to \infty$. When the limit term is zero $\lim_{n \to \infty} \delta_n B_n = 0$, this means that in the long run we rule out a Ponzi scheme where the government is 'bubble' financing its expenditure by issuing new debts to finance the deficits. Therefore, a fiscal policy will be sustainable if the limiting term is zero.

---

[1] The interpretation of the interest rate in Equation (1) depends on how total government expenditures and revenues are measured. When the variables are nominal, r_t is the nominal interest rate; when the variables are real, r_t is the real interest rate; when the variables are real per real GDP, r_t is the real interest rate minus the rate of growth in real GDP; and when the variables are real per capita, r_t is the real interest rate minus the rate of population growth (Hakkio and Rush, 1991).

However, Equation (2) given is not an appropriate equation for the empirical testing. Following, the literature on the host subject, we assumed that the interest rate is stationary around a mean r or expressed as the real interest rate. In order to transform the equation into some testable implication and after further manipulation, Equation (2) may also be written as

$$RG_t - RR_t = \sum_{s=0}^{\infty} \frac{\Delta RR_{t+s} - \Delta RG_{t+s} + r\Delta B_{t-1+s}}{(1+r)^{s-1}} + \lim_{s \to \infty} \frac{B_{t+s}}{(1+r)^{s+1}} \tag{3}$$

where RG_t represent the total government spending on goods and services and transfer payments and interest on the debt or $RG_t = G_t + rB_{t-1}$. Following Hakkio and Rush (1991), we assume that the RR_t and $G_t + (1+r)B_{t-1}$ are nonstationary variables of $RR_t = \alpha_1 + RR_{t-1} + \varepsilon_{1t}$ and $RG_t = \alpha_2 + RG_{t-1} + \varepsilon_{2t}$. Consequently, Equation 3 can be rewritten as

$$RG_t = \alpha + RR_t + \lim_{s \to \infty} \frac{B_{t+s}}{(1+r)^{s+1}} + \varepsilon_t \tag{4}$$

where $\alpha = \frac{1+r}{r}(\alpha_1 - \alpha_2)$ and $\varepsilon_t \sum_{s=0}^{\infty} \frac{(\varepsilon_{1t} - \varepsilon_{2t})}{(1+r)^{s-1}}$.

Equation (4) forms the basis of the testable hypothesis. If the transversality[2] condition holds, the limit term in Equation (4) is zero and rewriting Equation (4) we obtained

$$RR_t = a + bRG_t + \mu_t \tag{5}$$

along with the null hypothesis of $b = 1$ and μ_t stationary process. Equation (5) has been used as the basis to assess the sustainability of government intertemporal budget constraint in the literature. Following the work of Quintos (1995) and Martin (2000), four scenarios of the sustainability conditions can be identifies as follows:

(a) The deficit is 'strongly' sustainable if and only if the *I(1)* processes of RR and RG are cointegrated with cointegrating vector [1,-1]or with $b = 1$. It means that the government budget constraint intertemporally holds and at the same time, the undiscounted debt process B_t is *I(1)*.

(b) The deficit is 'weakly' sustainable if and only if RR and RG is cointegrated with the coefficient of b expressed as $0 < b < 1$[3].

(c) The deficit is unsustainable if $b \le 0$. An unsustainable deficit is the condition which implies that the debt process of B_t is exploding at the rate equal to or in excess of the growth rate in the economy, such that the limiting term in government intertemporal budget constraint of Equation (2) is violated.

(d) The condition where $b > 1$ is not consistent with a deficit. It implies that the government revenues are growing at the faster rate than the government expenditures (Martin, 2000).

ECONOMETRIC METHODOLOGY

Unit root tests

In carrying out the cointegration analysis, the first step is to implement the unit root tests. For this purpose, we deployed the Said and Dickey (1984, ADF) and the stationary test by Kwiatkowski *et al.* (1992, KPSS). The ADF test is based on the null hypothesis that a unit root exists in the time series. In contrast, the KPSS procedure tests for level (η_μ) or trend stationarity (η_τ) against the alternative of a unit root. Briefly, the KPSS test statistic for level (trend) stationary is expressed as

---

[2] The transversality condition requires a zero limit of future government debt discounted at a rate that depends on the probability distribution of future debt and not in the government bond rate. In this sense, transversality condition is to rule out Ponzi schemes. When we rule out the Ponzi schemes, the fiscal policy will be sustainable (see Equation 2 of the main text).

[3] Hakkio and Rush (1991) demonstrate that $0 < b < 1$ is a sufficient criterion for the deficit to be sustainable. However, the condition of $b < 1$ implies that the government expenditure will always be larger than revenue. In this limit, the undiscounted stock of debts will reach infinity and makes the value of debt unbounded that provides incentives for government to default on its debt. Therefore, this is the less desirable scenario.

$$\eta_\mu(\eta_\tau) = \frac{1}{s^2(k)T^2} \sum_{t=1}^{T} S_t^2 \qquad (6)$$

where $S_t = \sum_{i=1}^{t} u_i$, u_t are the residuals from the regression of X_t on a constant (a constant and trend) for the level (trend) stationarity, $s^2(k)$ is the non-parametric estimate of the 'long run variance' of u_t while k stands for the lag truncation parameter. Its combined use with ADF tests is likely to enable more clear-cut conclusion on the requirement of the order of integration when applying time series data.

Multivariate Cointegration Procedure

The determination of the number of cointegrating vectors based on Johansen and Juselius (1990, JJ) multivariate procedure depends on the use of two likelihood ratio (LR) test statistics: the trace test and the maximum eigenvalue test. The JJ procedure is the popular in the empirical testing of time series literature and the detail explanations are not presented here. Critical values for both the trace and maximum eigenvalue tests are tabulated in Osterwald-Lenum (1992).

The importance of applying a degree-of-freedom correction for the JJ procedure in small samples is well known. The correction factor is necessary to reduce the excessive tendency of the test to falsely reject the null hypothesis of no cointegration often associated with data of a relatively short span. Cheung and Lai (1993) provide the correction factor for small sample sizes of the JJ likelihood ratio tests while Reinsel and Ahn (1992) suggest an adjustment to the estimated trace and maximum eigenvalue statistics. The degree-of-freedom correction suggested by Reinsel and Ahn (1992) is to multiply the test statistic by *(T-pk)/T*, where *T* is the sample size, *p* is the number of variables, and *k* is the lag length of the VAR model. In the analysis that follows, we relied on the latter suggestion to check for the significance and the robustness of the cointegration results from the JJ procedure.

Gregory and Hansen Cointegration Method

The JJ approach has its limitations especially when dealing with a long data span may be affected by major economic events. Several studies have documented the sensitivity of the outcome of the JJ tests to structural breaks (Wu, 1998; Lau and Baharumshah, 2003)[4]. Given that such breaks are likely to exist in estimating a cointegrating relationship, we apply the Gregory and Hansen (1996, GH) cointegration tests that account for an endogenously determined break.

Briefly, the approach is similar to the Engle-Granger two-step procedure, except the dummy variables ($D_{t\tau}$) are included in the cointegrating regression to account for a shift in the long-run relationship. The advantage of this test is the ability to treat the issue of a break (which can be determined endogenously) and cointegration altogether. In their paper, Gregory and Hansen had provided a set of residual-based cointegration tests that allow for (i) level shift, (ii) level shift with trend and (iii) regime shift alongside with the asymptotic critical values for their tests.

Specifically, the models are estimated (separately) as follows, which tallies the model 2, 3 and 4 in Gregory and Hansen (1996).

Model 2: Level Shift (C)
$$RR_t = \mu_1 + \mu_2 D_{t\tau} + \delta^T RG_t + e_t \qquad t=1,...n \qquad (7)$$

Model 3: Level Shift with Trend (C/T)
$$RR_t = \mu_1 + \mu_2 D_{t\tau} + \psi t + \delta^T RG_t + e_t \qquad t=1,...n \qquad (8)$$

Model 4: Regime Shift (C/S)
$$RR_t = \mu_1 + \mu_2 D_{t\tau} + \delta_1^T RG_t + \delta_2^T RG_t D_{t\tau} + e_t \qquad t=1,...n \qquad (9)$$

and

---

[4] Authors like Quintos (1995), Papadopoulos and Sidiropoulos (1999) and Martin (2000) also documented the importance of the unusual exogenous events that may altered the conduct of fiscal policy in a country and the stress need for allowing the structural break in examining the sustainability of fiscal policy.

$$
D_{t\tau} = \begin{cases} 0 \; \textit{if } t \leq [n\tau], \\[2mm] 1 \; \textit{if } t > [n\tau], \end{cases}
$$

where μ_1 represents the intercept before the shift, μ_2 represents the change in the intercept at time of the shift, and t is a time trend. The unknown parameter $\tau \in (0, 1)$ denotes the (relative) timing of the change point and $[\ ]$ denotes integer part. The parameter δ_1^T denotes the cointegrating slope coefficients before the regime shift while δ_2^T denotes the change in the slope coefficients in Equation (8) which are consider the most general case that consider one time break point in both constant and trend (regime shift)[5].

The estimation of the relevant regression is performed sequentially in each breakpoint and calculated using the range of $\hbar = [0.15, \quad 0.85]$ interval. The breakpoint is identified as the one where the GH test statistic is maximized the absolute value at which the structural break occurred. The advantage of the GH procedure is that it determines the break point endogenously from the data set rather than on the basis of *a priori* information. Hence, the problem of data mining can be avoided by employing this procedure.

Estimation of Long run Equilibria

The JJ procedure may be used to extract the long-run parameters of the model. However, a more robust method proposed by Stock and Watson (1993) that also corrects for possible simultaneity bias among the regressors is considered in this paper[6]. The method involves estimation of the long-run equilibrium relationship using the dynamic OLS (DOLS) method. In this study, we relied on the technique devised by Stock and Watson (1993) that allows the (dynamic) estimation of cointegrating vectors for the system involving deterministic components.

Data Description

The empirical estimation period begins in 1975Q1 and ends in 2003Q2. In order to examine the effect of the 1997/98 currency crisis on the sampled economies, we also consider sub-sample periods. First, is the pre-crisis period starts in 1975:Q1 and ends in 1997:Q2. This period is coincides with the rapid growing phase of these crisis-affected countries. The second is the post-crisis period reflects the inclusion of the currency crisis era and the subsequent recovery years (1975:Q1-2003:Q2). Quarterly observations of the total government revenues and government expenditures (inclusive of the transfer payments and interest on the debt) and gross domestic product (GDP)[7] are sourced from International Monetary Fund's *International Financial Statistics* (IFS). The total government revenues and expenditures are converted into real terms by using the consumer price index (CPI 1995=100) and divided to real GDP in order to account for the economy's growth[8]. The real budget balances (BD) is constructed using BD = RR – RG. All the variables are expressed in domestic currency.

EMPIRICAL INVESTIGATION

Univariate Unit Root Tests Results

Table 1 displays the empirical results of the univariate tests performed on RR, RG and BD. Overwhelmingly, all the testing procedures suggest the existence of unit root in level or $I(1)$ series for all these countries. The finding

---

[5] The dummy variable, $(D_{t\tau})$ is a sequence of zeros prior to the break point and ones thereafter. Specifically, for each τ, estimation of the above models (depending upon the alternative hypothesis) by OLS, yields the residuals $\hat{e}_{t\tau}$.

[6] They offer a parametric approach for estimating long-run equilibria in the system that involve variables integrated of different orders but still cointegrated. The possibility of simultaneity bias and small sample bias among the regressors is dealt with the inclusion of lagged and lead values of the first difference in the regressors. Moreover, Monte Carlo results show that the DOLS estimator has the lowest root mean square error (RMSE) and, therefore, performs well in finite samples relative to other asymptotically efficient estimators.

[7] Quarterly observations of GDP were extrapolated from the annual series employing the Gandolfo (1981) approach. For more detail exposition of the procedure see, Lau and Baharumshah (2004).

[8] The assumption of stationary interest rate rules out nominal magnitudes of the data since the nominal interest rate is the nonstationary variable (Hakkio and Rush, 1991).

that all the variables has the same order of integration allow us to proceed with the JJ multivariate cointegration analysis. Interestingly, BD also appears to be the nonstationary for these countries suggesting that the fiscal policies are on the unsustainable path for the sample period (Trehan and Walsh, 1991)[9].

Notes: The t and η statistics are for ADF and KPSS respectively. The subscript μ in the model allows a drift term while τ allows for a drift and deterministic trend. Please refer to the main text for the notations. Asterisk (*) show significance at 5 percent level. The asymptotic and finite sample critical values for ADF is obtained from MacKinnon (1996) while the KPSS test critical values is obtained from Kwiatkowski *et al.* (1992, Table 1, pp. 166). The ADF examine the null hypothesis of a unit root against the stationary alternative while KPSS tests the null hypothesis that the series is stationary against the alternative hypothesis of a unit root. Δ denotes first different operator. To select the lag length, we adopted the recursive *t*-statistic procedure by Ng and Perron (1995) with an upper bound of k_{max} = 12. If the last included lag is significant, we would choose $k= k_{max}$. If not, we would reduce *k* by one until the last lag becomes significant. If no lags are significant then *k* is set to zero (*k*=0). The 5 percent value of the asymptotic normal distribution, 1.96 is used to assess the significance of the last lag. Figures in parentheses are the optimal lag lengths.

JJ Cointegration Results

We adopted the Akaike's information criterion (*AIC*) to determine the optimal lag length. The criteria yields VAR(5) is more appropriate for Malaysia and the Philippines while VAR(3) for Thailand. Despite the different lag length employed in the analysis, the residuals for each equation in the system do not exhibit any form of serial correlation or autoregressive conditional heteroskedasticity (ARCH) effects.

Table 2 presents the JJ cointegration test results. In general, the null hypothesis of no cointegrating vector in Panel A (post-crisis period) is rejected at 5 percent significance level for all the countries. Rejecting the null hypothesis of no cointegration between the *I*(1) variables appearing in Equation (5) implies that the two variables do not drift apart in the long-run.

Next, we re-examine the long run relationship using data that ends in 1997:Q2 (Panel B). The purpose is to test and compare the differences between the pre- and post-crisis periods for these economies in governing the macroeconomics of fiscal policy. As indicate in Panel B, the null hypothesis of no cointegrating vector (r=0) is

---

[9] We also tested the univariate properties for the period between 1975:Q1 and 1997:Q2. The verdict is also in agreement with the *I(1)* properties for all the series. The results are not reported for the reasons of brevity.

rejected at conventional significance levels solely for Thailand. For the remaining countries, the data fail to reject the null of no cointegration, thus suggesting these countries were having problems with their internal imbalances. The absence of cointegration between the two variables system (RR, RG) in these two cases implies that there is no relationship between revenues and expenditures in the government financial structure for the sample period that ends in 1997:Q2. Also, the inability to reject the null of no cointegration in the majority of cases examined above might be due to the existence of structural break(s) that bias the test results in favor of accepting the null. This leads us to pursue further testing using an alternative procedure that can accommodate potential structural breaks in the data.

Notes: Asterisk (*) denote statistically significant at 5 percent level. The k is the lag length and r is the cointegrating vector(s). Chosen r: number of cointegrating vectors that are significant under both tests. The unadjusted and the adjusted statistics are the standard JJ test statistics and the statistics adjusted for small sample correction factor based on Reinsel and Ahn (1992) methodology.

Structural Break Results

Table 3 summarized the results of the GH cointegration and the figures tabulated in the brackets indicate the break points detected from each of the particular model. For post-crisis period (Panel A), the first model (mean model) reveals that cointegration is present with a break only for Thailand (1988:Q3), implying that the data supports cointegration with one change in the intercept. The second model (level shift and trend model) failed to detect any significant presence of cointegration with a break for all the countries. Finally, the third model that takes into consideration of the simultaneous presence of both a mean break and a slope break (regime shift) exhibits empirical support for the case of Malaysia (1988:Q2) and the Philippines (1988:Q2). Meanwhile in Panel B (pre-crisis period), we only found cointegrating relationship between revenues and expenditures for Thailand. This finding appears to support the JJ test reported earlier in Table 2. Indeed, both of the cointegration tests indicated that Thailand are on the sustainable path (weak form) in governing the financial structure of the country. For the remaining countries, the results reveal that the countries are on an unsustainable path for the pre-crisis period.

Table 3: GH Cointegration Tests

Country	C	C/T	C/S
A: Period: 1975:1-2003:2			
Malaysia	-2.018	-4.069	-5.936*
	[1997:2]	[1988:2]	[1988:2]
Philippines	-2.184	-4.212	-5.262*
	[1989:1]	[1989:1]	[1988:2]
Thailand	-6.312*	-4.022	-7.307*
	[1988:3]	[1988:2]	[1989:2]
B: Period: 1975:1-1997:2			
Malaysia	-2.840	-2.534	-3.745
	[1988:2]	[1988:3]	[1989:1]
Philippines	-2.945	-2.485	-3.335
	[1993:1]	[1993:2]	[1993:1]
Thailand	-4.004	-3.807	-8.478*
	[1987:1]	[1989:1]	[1988:4]

Note: Asterisk (*) denote statistical significance at the 5 percent level. The critical values for models C [-4.61], C/T [-4.99] and C/S [-4.95] are obtained from of Gregory and Hansen (1996 Table 1 pp.109). Figures in [ ] refers to the breaking date.

The break points detected in the late 1980s by the GH test coincide with some major international events. First, the collapse of commodity prices due to the world recession (Plaza Accord and its aftermath) in the mid-1980s. The impact of such economic phenomena contributes to the significant break detected in the countries in the region. Second, the introduction of the Brady Plan in late 1980s that articulated new principles for addressing the LDC debt crisis with the focus on the Latin America countries. We move to the next section, by testing the necessary and sufficient condition (strong form) of sustainability hypothesis that would mitigate a clear conclusion on the subject matter.

Estimation of Long run Equilibria

The DOLS estimation results appear in Table 4. We also test whether the cointegration coefficient $b = 1$ (strong form of sustainability condition) is insignificantly different 1. First, we found that the null hypothesis of $b = 1$ is strongly rejected for Malaysia (Panel A), the Philippines (Panel B) and Thailand (Panel D) that supports the weak form of sustainability. This condition implies that the government expenditures are growing at the faster rate than the revenues. For example, an increase of RM 1.00 of government expenditures in Malaysia would rise the revenues by only RM 0.778. Following this development, the undiscounted stock of debts will reach infinity and makes the value of debt unbounded. This in turn would provide the incentives for this government to default on its debt. This supports the second scenario of sustainability condition outlined earlier.

Second, the DOLS results provide enough evidence to satisfy the solvency condition of the government intertemporal budget constraint (strong form of sustainability) only for Thailand (Panel C). This implies that the undiscounted value of the public debt goes to zero (transversality condition holds). As reported in ADB (2004) the Thai's economy had grown faster in 2003 than most other countries in the region. This fast economic expansion had strengthened the fiscal position, mainly through mounting tax revenues. With its first fiscal surplus amounting to 0.6 percent of GDP in 2003, the economy is in a position to generate a cushion to address a future slowdown using injections of government spending. This evidence also implies that despite the economic turmoil in 1997, the government of Thailand managed their financial structure efficiently while committed to the fiscal consolidation assessment in achieving the future positive growth prospects of the country.

Table 4: Dynamic OLS Estimation (DOLS)

Country	b	H_0: b = 1	AR(5)	ARCH (4)	RESET(4)	J-B	White
A: Malaysia (1975:1-2003:2)							
Model C/S	0.778	36.777*	1.503	1.730	1.895	1.973	0.682
B: Philippines (1975:1-2003:2)							
Model C/S	0.789	29.033*	2.324	2.201	0.265	0.741	0.849
C: Thailand (1975:1-2003:2)							
Model C/S	0.959	1.102	0.783	0.051	0.575	1.903	0.364
D: Thailand (1975:1-1997:2)							
Model C/S	0.842	7.342*	1.446	1.826	2.173	2.993	1.314

Note: The distributional properties of diagnostics are: LM (5) is a test of 5nd order serial correlation. ARCH (m) is an m-order test for autoregressive conditional heteroskedasticity. Ramsey's RESET (Regression Specification Test) test uses the square of the fitted values. J-B (Jarque-Bera) is the test of the normality of the residuals. The White general heteroscedasticity test is based on the regression of squared residuals on squared fitted values. Asterisks (*) denote significance at percent level. The break point selected for the DOLS estimation is based on the Gregory and Hansen results from Table 3. For Thailand, the break points are chosen on the basis of model C/S in both sampling periods.

Third, the estimated model that appears in Table 4 seems to be robust to various departures from the standard regression assumptions in terms of serial correlation of the residuals, autoregressive conditional heteroskedasticity (ARCH) effects, misspecification of functional form (RESET test), non-normality (Jarque-Bera test) and heteroskedasticity of residuals (White test). Furthermore, the CUSUM squares stability test is conducted for each of the estimated model. If the plot of the CUSUM squares sample path moves outside from the critical region (5 percent significant level), the null hypothesis of stability over time for the intercept and slope parameters is rejected (assuming the model is correctly specified). Using the empirical findings in Table 4, one may construct visual illustrations of 4 possible scenarios of CUSUM squares paths. Figure 1 plots the graphical paths of the CUSUMSQ test for these countries. Visual inspection for all the countries reveals that the plot of CUSUMSQ test fluctuates inside the 5 percent critical band. This implies that over the estimated period, the models are indeed stable and well specified.

Figure 1: CUSUM of Squares Test

(d) Thailand (1975:1 – 1997:2)

SUMMARY AND POLICY CONCLUSIONS

This paper tests whether the long run fiscal policy in three crisis-affected ASEAN countries is consistent with the sustainable condition by satisfying the government intertemporal budget constraint in the present value terms. These countries recorded budget imbalances in some of the years while surplus in the other years throughout the estimation periods. Using the critical statistical analysis, we outlined several important findings as follows.

First, prior to the crisis, revenues and expenditures do not share a common stochastic trend in such a manner that the internal imbalances were consistent with the government intertemporal budget constraint for most of the countries under investigation. In other words, we find the evidence of violation of the government intertemporal budget constraint prior to the crisis (strong form) and the weak form for Thailand. The growing fiscal imbalances in these countries had widened the current account deficit due to the close connection between them, termed as twin deficits. Specifically, the rise in the budget deficits leads to the appreciation of the currency that will adversely affected the current accounts for these countries (Lau *et al*, 2004). These further cause the macroeconomic imbalances and it distort the long-term economic progress of a country (Edwards, 2001 and Megarbane, 2002).

Second, in the post-crisis era it was observed that only Thailand is on a sustainable path (in strong form). In other words, the discounted value of the debt tends to converge to zero over time. There is no indication that the government of Thailand will tend to default on their debts. The possible action taken by the authorities had brought back the sustainability of fiscal position for Thailand. Meanwhile, the 1997 financial turbulence leaves the permanent unsustainable pressure to the Malaysian and the Philippines fiscal policies. In other words, these countries face the problem of having higher indefinite continuation of growth rate for expenditures compared to the growth rate of revenues. In the response to the post-crisis slowdown, both of the countries (especially Malaysia) actively implement the expansionary fiscal policies. For example, several stimulus packages covering a wide range of initiatives were implemented to rise spending and encourage private investment and consumption in Malaysia. These results also support the deficits recorded in the post-1997 periods for the two countries.

Third, we found that the government fiscal positions vary significantly across these countries. Despite the differences, the needs for fiscal consolidation and prudent fiscal policies instruments are essential for reducing public debt, improving operation of monetary and exchange rate policies while facilitating private sector-led growth. Consolidation in fiscal policy assists long term growth since countries with low deficits and debt levels can exercise more options over expenditure priorities and allocate more resources to productive sectors. Therefore, assessing, monitoring and maintaining stable and sustainable fiscal position is the key elements of the macroeconomic stability for an economy. These would bridge the road towards broader desire for economic, monetary and financial cooperation in the ASEAN region.

ABSTRACT

The Euro was adopted as the common currency among 12 out of 25 members of the European Union (EU). Many economies are eager to heed the same path as the EU in the name of promoting trade, eliminating exchange rate uncertainty, and sustaining economic growth. However, potential members will have to at least demonstrate some form of macroeconomic interdependence or synchronisation prior to the formation of an economic union. In this study, we examine the level of economic interdependence among several countries within the Asia-Pacific region. We employed the augmented VAR of Granger non-causality test in order to apprehend the level of synchronisation and interdependence among these countries. The empirical findings support APEC's effort of economic co-operation that will pave the way for a possible Asia Pacific economic union in the near future.

INTRODUCTION

The success adopting of Euro has sparked the interest in the field of economic and monetary integration, especially among developing economies in the Asian region. The reason causing such eagerness is that an integrated economy has the potential in promoting trade, reducing transaction cost, eliminating exchange rate uncertainty, and sustaining economic growth.

Earlier studies on economic integration have centred on the optimum currency area (OCA) theory. The OCA theory stressed on the importance of labour mobility (Mundell, 1961), openness of an economy (McKinnon, 1963) and product differentiation (Kenen, 1969) as criteria necessary to form an OCA. Based on these fundamental criteria, recent researchers proposed other essential elements that are pre-requisites to form an OCA, namely having stable or fixed exchange rate, facing symmetrical shocks, increasing trade and capital flows, experiencing coherent macroeconomic activities where fiscal and monetary are co-ordinated.

Besides these OCA criteria, the possibility of an economic union can also be determined by conducting a marginal benefits – marginal cost analysis of integration. Only when the benefits in terms of increased trade, foreign direct investment and economic growth, exceeds the cost of giving up monetary policy independence, that potential members should proceed to form an economic union.

As for the case of the European Monetary Union, it evaluates the compatibility of economies through institutional convergence criteria. The EU established a set of "convergence criteria" to be fulfilled by countries

desired to adopt the common currency Euro. Countries that fulfil the convergence criteria that are specifically spelt out in the Maastricht Treaty will be eligible to form Euro area.

The purpose of this paper is to provide an initial avenue of the prospect of Asia-Pacific Economic Co-operation (APEC) economies to form a union. In this study, we employed the correlation analysis and the augmented VAR of Granger non-causality test in order to gauge the level of interdependence among APEC economies. A strong level of economic interdependence suggests possible policy co-ordination for greater Asia-pacific integration and a weak interdependence suggests otherwise.

In the next section of this paper, we present a brief review of some related literature, to be followed by a discussion on the estimation techniques used and empirical results obtained. We end our discussion by offering some concluding remarks.

PREVIOUS STUDIES

Based on the World Development Indicators (2000), there are four main groups of economic blocs, namely, the Asia Pacific, European and North American bloc, the Latin American and the Caribbean, African, as well as the Asian economic blocs. The *Asia Pacific Economic Co-operation (APEC)* is classified under the Asia Pacific, Europe and North American economic blocs, which also include the *European Union (EU)* and the *North American Free Trade Association (NAFTA)*.

Generally, economic integration refers to economic interdependence or linkages between states, countries, and grouping of countries or regions. The flow of trade, capital, labour and technology across countries are evidence of economic linkages (O'Neill, 2002). The degree of economic integration, however, ranges from establishing free trade areas, customs unions, common markets, economic and political unification among member nations (Balassa, 1961).

Mundell (1961), McKinnon (1963) and Kenen (1969) provide a theoretical basis from which the formation of monetary integration is examined. In more recent studies, more criteria were introduced and other measures were designed to test the compliance of OCA theory among countries wanting to form a common currency. These recent studies re-tested the existing criteria as well as proposed other criteria complementing the existing OCA properties (see Shin and Wang, 2003; Sayek and Selover, 2002; Mongelli, 2002; Kose and Engel, 2002; Choe, 2001).

Studies that examined the compatibility of Asian or Asia Pacific economy to form an economic integration include those conducted by Crosby, 2003; Hallett and Piscitelli, 2002; O'Neill, 2002; Dueker and Wesche, 2001; Clark and Wincoop, 2001; Choe; 2001; Ling, 2001; Bayoumi and Maoro, 1999; Dent, 1998; Bayoumi and Eichengreen, 1994. This paper attempts to fill the gap in literature by studying the interdependence of Asia Pacific economies with more annual data for sampling period between 1960 to 2002.

ESTIMATION TECHNIQUE

Using logged data, we employ the augmented VAR procedure introduced by Toda and Yamamoto (1995), extended by Rambaldi and Doran (1996). The augmented VAR method guarantees the asymptotic distribution of MWald statistic and does away with the problem of co-existence of both a unit root and cointegration (Zapata and Rambaldi, 1997).

The augmented VAR utilises a modified WALD test for restrictions on the parameters of a VAR(ρ) or MWald procedure, where k is the lag length in the system, and is shown by Rambaldi and Doran (1996), computed as Seemingly Unrelated Regression (SUR). To perform the Granger non-causality test, it is required to determine a lag length (k), and to estimate $(k + d_{max})$ order of VAR formulated in levels where d_{max} is the maximum order of integration suspected to occur in the system.

We choose the true lag length (k) using the Schwart Bayesian Criterion (SBC). If the lag length, k is 1, we set our estimation of the system of SUR VAR(2) that is where k=1 and d_{max}=1. We estimate our system of VAR ($\rho = d_{max} + k = 2$) as follows:

$$
\begin{bmatrix} YMY_t \\ YPH_t \\ YSP_t \\ YTH_t \\ YID_t \\ YAU_t \\ YJP_t \\ YNZ_t \end{bmatrix} = A_0 + A_1 \begin{bmatrix} YMY_{t-1} \\ YPH_{t-1} \\ YSP_{t-1} \\ YTH_{t-1} \\ YID_{t-1} \\ YAU_{t-1} \\ YJP_{t-1} \\ YNZ_{t-1} \end{bmatrix} + A_2 \begin{bmatrix} YMY_{t-2} \\ YPH_{t-2} \\ YSP_{t-2} \\ YTH_{t-2} \\ YID_{t-2} \\ YAU_{t-2} \\ YJP_{t-2} \\ YNZ_{t-2} \end{bmatrix} + A_3 \begin{bmatrix} \varepsilon_{YMY_t} \\ \varepsilon_{YPH_t} \\ \varepsilon_{YSP_t} \\ \varepsilon_{YTH_t} \\ \varepsilon_{YAU_t} \\ \varepsilon_{YJP_t} \\ \varepsilon_{YNZ_t} \end{bmatrix}
$$

where, YMY_t is the nominal GDP of Malaysia at time t; YPH_t is the nominal GDP of Philippines at time t; YSP_t is the nominal GDP of Singapore at time t; YTH_t is the nominal GDP of Thailand at time t; YID_t is the nominal GDP of Indonesia at time t; YAU_t is the nominal GDP of Australia at time t; YJP_t is the nominal GDP of Japan at time t; YNZ_t is the nominal GDP of New Zealand at time t; ε_t is the error term; A_1 and A_2 are eight times eight matrices of coefficient and A_0 is an identity matrix.

To test the hypothesis, that non-Granger causality from YPH_t to YMY_t, we test $H_0 : a_{12}^1 = a_{12}^2 = 0$, where a_{12}^i are coefficients of YPH_{t-1} and YPH_{t-2} in the first equation of the system stated above. A causality from YPH_t to YMY_t can be established through rejecting the above null hypothesis which requires finding the significance of the MWald statistic for the group of the lagged independent variables identified above. Alternatively, testing procedure can be applied to the alternative hypothesis that non-Granger causality from YMY_t to YPH_t by testing $H_0 : a_{21}^1 = a_{21}^2 = 0$, where a_{21}^i are the coefficients of YMY_{t-1} and YMY_{t-2} in the second equation of the system. Similar testing procedure is repeated to test Granger non-causality for the remaining variables.

In this paper, we use annual time series of nominal GDP, measured in domestic currency for the sampling period from 1960 to 2002. We obtained our data from the International Financial Statistics published by the International Monetary Fund.

EMPIRICAL FINDINGS

The correlation matrix of GDP for ASEAN-5, Australia, New Zealand and Japan of reveals strong relationship among the economies under study. The positive correlation coefficient shown in Table 1 reveals strong direct association between GDP of each ASEAN-5 countries, Australia, New Zealand, and Japan.

Table 1: Correlation Matrix of Variables

	Australia	Indonesia	Japan	Malaysia	New Zealand	Philippines	Singapore	Thailand
Australia	1.0000	0.9197	0.9742	0.9920	0.9988	0.9970	0.9961	0.9956
Indonesia		1.0000	0.9682	0.8958	0.9112	0.9087	0.9221	0.9103
Japan			1.0000	0.9502	0.9712	0.9607	0.9721	0.9617
Malaysia				1.0000	0.9883	0.9971	0.9952	0.9973
New Zealand					1.0000	0.9946	0.9931	0.9928
Philippines						1.0000	0.9968	0.9980
Singapore							1.0000	0.9975
Thailand								1.0000

For the augmented VAR analysis, the true lag length (*k*) is determined via the Schwart Bayesian Criterion (SBC), which is presented in Table 2.

Table 2: Choice Criteria for Selecting the Order of the VAR Model

NLagr	SBC
1	194.65*
2	189.93
3	183.02

Note:
  i)   SBC = Schwarz Bayesian Criterion
  ii) Nlag = the number of lags used in VAR
  iii) * shows the largest value of SBC

From Table 2, the highest SBC value indicates that lag length $k=1$ is selected. Hence, we run the augmented VAR(2). The results for VAR(2) revealed that the null hypothesis of Granger non-causality from GDP of Indonesia to GDP of Japan and New Zealand is rejected at 5% level. The null hypothesis of Granger non-causality from GDP of Japan to GDP of Malaysia, Philippines, Singapore and Thailand are also rejected at 5% level. At 5% level, Granger non-causality from GDP of Malaysia to GDP of Indonesia and Philippines; GDP of Philippines to GDP of Malaysia; as well as GDP of Singapore to GDP of Australia; are all rejected.

The null hypothesis of Granger non-causality from GDP of Thailand to GDP of Singapore is also rejected at 1% level of significance. In addition, GDP of Australia, Indonesia, Japan, New Zealand, Malaysia, Philippines, Singapore and Thailand are found to be influence by its own GDP of lag 1 at 1% level.

Besides, bi-directional causality is discovered from GDP of Malaysia and Philippines at 5% level, GDP of Indonesia and Japan at 10% level, and GDP of Singapore and Japan at 10% level. The output of these augmented VAR Granger non-causality tests are presented in Table 3.

  iii) * denotes significant at 5% level.

CONCLUDING REMARKS

In this paper, we explore the prospects of APEC forging an economic integration by examining the interdependence of ASEAN-5, Australia, New Zealand and Japan macroeconomic activities via the augmented VAR of Granger non-causality test. Our findings suggested that there is some interdependence among ASEAN-5, and Japan, the leading economy in East Asia.

There is also evidence of bi-directional causality among Malaysia and Philippines, Indonesia and Japan, as well as Singapore and Japan. These initial findings support APEC's effort of economic co-operation that will pave the way for a possible Asia Pacific economic union in the near future.

ABSTRACT

Over the past few years, Foreign Direct Investment (FDI) has played an enormous role in the development and growth of the Malaysian economy.At the initial stage, most of these FDI flowed into the manufacturing sector due to the availability of cheap and abundant manual labour. The pro-active strategies of the Malaysian government that came up with numerous incentives and open door policy further attracted MNCs to locate their production plants here. However, as Malaysia grew rapidly over the last few years, the scenario slowly shifted when labour cost started to rise rapidly in the 1990s. Malaysia became less attractive for FDI in labour intensive manufacturing and some MNCs even decided to relocate their plants to neighbouring countries such as Indonesia, Thailand, Vietnam and even China that offered much cheaper labour. Since the financial crisis hit Malaysian in 1997, the slowdown of FDI inflows has been a key concern. In the mid 1990s, due to accelerating labour costs, the government started to emphasise more on the service sector and has identified it as a key area of growth in the future. This was in line with plans to shift away from a production-based to a knowledge-based economy. The service sector is poised to be the main engine of growth in the future. The proliferation of the information and communication industry and further deregulation and liberalisation have spurred the consumption of services, particularly in finance, transport and telecommunication sectors. The factors influencing FDI into the manufacturing sector may not be the same for the services sector.As such, it is imperative that more emphasis is given to FDI research in services since there is scarcity of theoretical frameworks in this area. In fact, theory seems to be lagging behind practice in the internationalisation of services research (Clark et al. 1996 cited in Gronroos 1999, p.9).The main objective of this research is to examine and analyse FDI by MNCs in the Malaysian services sector. This paper attempts to develop a conceptual framework that will be used for future research in identifying the factors influencing FDI in the Malaysian service sector. Although there are many factors influencing FDI by MNCs in general, it is still not clear if these factors also apply to the service sector.

_____

INTRODUCTION

Background to the study

There are many definitions of Foreign Direct Investment (FDI). For the purpose of this research, the FDI definition by United Nations Conference on Trade and Development (UNCTAD) is used. FDI is defined by UNCTAD (2002) as the following:

> 'FDI is defined as an investment involving a long term relationship and reflecting a lasting interest and control of a resident entity in one economy in an enterprise resident in an economy other than that of the foreign direct investor. An equity capital stake of 10% or more of the ordinary shares or voting power of an   incorporated enterprise, or its equivalent for an unincorporated enterprise, is normally considered as a threshold for FDI'

It is however, important, to distinguish FDI from portfolio investment. Portfolio investments are purchases of foreign financial assets such as stocks, bonds and certificates of deposit (Griffin & Pustay 1998). The distinguishing factor here is control. In the case of portfolio investment, there is usually no interest to obtain control over an enterprise. Portfolio investment is usually undertaken to acquire financial returns. Since, this research is confined to the services sector in Malaysia, the emphasis will be on FDI by Multinational Companies (MNCs) in services that are commercially present in the host country. This investment will be referred to as throughout this research as service FDI and the foreign investors will be referred to as service MNCs.

Foreign Direct Investment (FDI) has become one of the main forces of sustaining the high economic growth and development Malaysia has achieved over the years. The FDI was brought mainly by Multinational Corporations

(MNCs) from all over the world who not only brought capital but technology, management expertise etc. Due to shortage of funds domestically and the small size of the private sector, Malaysia became highly dependent on FDI brought by these MNCs. At the initial stage, most of these FDI flowed into the manufacturing sector due to the availability of cheap and abundant manual labour. The pro-active strategies of the Malaysian government that came up with numerous incentives and open door policy further attracted MNCs to locate their production plants here. However, as Malaysia grew rapidly over the last few years, the scenario slowly shifted when labour cost started to rise rapidly in the 1990s. Malaysia became less attractive for FDI in labour intensive manufacturing and some MNCs even decided to relocate their plants to neighbouring countries such as Indonesia, Thailand, Vietnam and even China that offered much cheaper labour.

Why is FDI so important? FDI has played an effective role as a source of financing to a lot of developing countries. Although the impact of FDI on economic development is debatable, there are many empirical findings that support its positive contributions. Research by Mbekeani (1999) on the impact of FDI on domestic investment, exports and economic growth showed positive relationship in Mexico and Malaysia. Another research by Larrain, Luis & Andres (2001) showed positive effect of FDI generated by Intel in terms of net exports, investment, wages and benefits and local purchases for the Costa Rican economy. Thomsen (1999) in his study on the role of FDI in 69 developing countries found that it not only stimulates economic growth but also has a larger impact than investment by domestic firms. Developing countries are thus, competing to attract FDI into their economy. There are many factors that attract the movement of FDI throughout the world. These factors may differ significantly from one location to another depending again on the attractiveness of the particular region or country.

RESEARCH PROBLEM

There is enormous literature available on the subject of FDI. However, most of the empirical and theoretical research has been investigating manufacturing and production FDI. Research on FDI in the service sector is very much lacking. This view is supported by Chandraprapalert (2000) in his research on FDI in Thailand and Von Der Ruhr (2000) in his research on FDI in services. Even the theories of FDI and MNCs were originally developed to explain FDI in the manufacturing sector and only lately its application is being extended to the services sectors (Tatoglu and Glaister 1998).

The slowdown of FDI inflows has been a key concern since the financial crisis. The overall value of FDI in 2002 was only 11.2 billion, a decline of 41% from 18.9billion in 2001(Nathan 2003). From 1997 to 2001, the overall decline was 8.6% per annum against a substantial increase of 20.4% per annum during the period 1980 - 1996 (Nathan 2003). This decline would have huge implications on the future development of the Malaysian economy. With further competition from China in attracting FDI, the overall FDI inflows may further deteriorate in the future.

Relying on tax incentives alone is not enough to woo FDI into Malaysia since most of our competitors are also offering similar if not better tax incentives (Lim 2002).In the mid 1990s, due to accelerating labour costs, the government started to emphasise more on the service sector and has identified it as a key area of growth in the future. This was in line with plans to shift away from a production-based to a knowledge-based economy. The service sector is poised to be the main engine of growth in the future. The proliferation of the information and communication industry and further deregulation and liberalisation have spurred the consumption of services, particularly in finance, transport and telecommunication sectors.

It was noted that service sectors share of GDP have been rising gradually from 46.8% in 1990 to nearly 57% in 2003 (Business Times, Tuesday, Feb 3 2004). This is actually in line with the country's steady program towards achieving industrialised nation status where services sector generally account for about 70% of GDP. Despite all these favourable indicators, the service sector is still highly regulated in Malaysia. The Malaysian Government still refuses to grant new licenses to private providers of telecommunication services or prohibit establishment of new foreign banks and expansion of existing foreign banks. However, the government has given full commitment to deregulate and liberalise the financial sector by 2007. The government must shift its emphasis to further attract FDI into the services sector since this area has vast potential for Malaysia in the future. The service sector is very important to an economy because services are inputs for all aspects of processing. The services sector provides much of the necessary infrastructure for investment and economic growth and its efficient delivery is important to improve an economy's overall productivity. The services sector is also a high technology and highly educated labour venture that could benefit Malaysia in terms of adding greater value to the services produced.

The factors influencing FDI into the manufacturing sector may not be the same for the services sector. Tatoglu and Glaister (1998) argued that some factors influencing FDI may be more important for services than for manufacturing and thus, there is a need to further uncover such differences. Services are known to have idiosyncratic characteristics where workers employed are more educated with higher level skills and as such are different from the manufacturing sector in attracting FDI (Erramilli and Rao 1993). Services are also different due to its intangibility, non-storability and non-transportability that make it unique in its own sense. There is a need therefore, to clear the void that exists and determine exactly whether the current determinants of FDI in the literature are applicable across the board for all industries or sectors.

Recently, a lot of foreign call centres have been establishing their base in Malaysia. This is another example of FDI in the service sector. According to Stephen Shepherd, Kelly Services Regional Director for Sales and Operation (Asia Pacific), Malaysia is becoming an important contact centre hub and a better choice for global companies to locate their call centres (Business Times, 26 December 2002). The Multimedia Super Corridor (MSC), the country's test bed for the development and application of sophisticated information technology is also a host to MNCs such as DHL, Alcatel Networks, Acterna, Shell IT, British American Tobacco, Scope International -Standard Chartered (Business Times, 23 April 2002). He further reiterated that many MNCs are even relocating their call centres from Singapore and the Philippines to Malaysia. Industries that are relying heavily in the contact centre services in the country are banking, telecommunications, insurance, transportation and logistics.

According to the Asian Call Centre Industry Benchmark Study in 2003, Malaysia has about 575 contact centres and is placed at par with Singapore, Thailand and Hong Kong (The Star, BizWeek 4 October 2003 p.27) . There is a need to investigate in detail what are the factors behind such decisions from foreign service MNCs. With liberalisation taking place rapidly in the services sector, there is poised to be greater competition to attract service MNCs in such industries in the near future. Malaysia needs to gear up to remain ahead and be more attractive than their neighbours who are fast catching up.

Lately, many MNCs are also setting up or relocating their regional Operating Head Quarters (OHQ) to Malaysia. Malaysia is therefore seen as an attractive location for setting up regional OHQs. This was part of a push by MNCs to outsource shared services to lower cost regions in the face of increased competition globally and cost pressures at home. By consolidating back room operations such as accounting for the entire region in one location, companies could save on staff, processing and hardware cost (Lee 2003). Regional OHQs also provide 'qualifying services' such as management administration, corporate financial advisory, training and treasury and fund management to its related companies outside the host countries (Lee 2003). There are currently over one hundred companies that have shifted their regional OHQs to Malaysia (Lee 2003).

According to Idris (2003), Malaysia is also an ideal regional hub for outsourced call centre operations due to its proximity to high growth centres around South East Asia and excellent telecommunication infrastructure with multilingual capable workforce. All these factors points out that Malaysia should focus on the services sector in order to get ahead of the learning curve and compete in a globalised economy. The thinning margins in manufacturing and the rise of China as the 'factory of the world' has left manufacturing dependent countries like Malaysia with little choice (Matthews 2003).

There is vast literature available on FDI but most of it emphasises on the study of manufacturing MNCs (Wilkins 1977; United Nations 1978; Tatoglu & Glaister 1998; Von Der Ruhr 2000; Molina Lacayo 2003 Li, Wang & Zhai 2003; Chandraprapalert 2000 and Gronroos 1999). One reason for this may be due to the strong dominance of manufacturing MNCs in the early stage of foreign expansion. However, service MNCs are beginning to play a more prominent role due to the huge contribution of services to GDP in most developed and newly developed countries. Today, the service sector contributes close to 70% to GDP in most developed countries (UNCTAD/WTO 2002).

As such, it is imperative that more emphasis is given to FDI research in services since there is scarcity of theoretical frameworks in this area (Herrero & Simon 2003). In fact, theory seems to be lagging behind practice in the internationalisation of services research (Clark et al. 1996 cited in Gronroos 1999, p.9).

RESEARCH QUESTIONS

The problem statement above has established that there is a need to uncover the underlying factors influencing the inflow of FDI into the services sector. Service MNCs internationalisation using FDI is a grey area that needs further investigation. With this respect, the following research questions are formulated to guide this research:

1. What are the factors influencing MNCs to engage in FDI in the Malaysian service sector?
2. Can traditional theories that explain FDI flows into the manufacturing sector be applied to the services sector?

RESEARCH OBJECTIVES

The main objective of this research is to examine and analyse FDI by MNCs in the Malaysian services sector. This paper attempts to develop a conceptual framework that will be used for future research tin identifying the factors influencing FDI in the Malaysian service sector. Although there are many factors influencing FDI by MNCs in general, it is still not clear if these factors also apply to the service sector. It is the aim of this investigation to uncover those factors that may be more relevant to service MNCs.

IMPORTANCE OF THE STUDY

Malaysia needs FDI to complement domestic investment for the purpose of increasing its wealth in today's globalised world. FDI has had enormous contribution to the economic development of Malaysia since the mid 80s. However, the scenario is fast changing, with many developing countries like China, Thailand and India competing aggressively to attract FDI. Since the 1980s, the government has been practicing a liberal policy towards FDI. Over the years, the government has provided numerous incentives to attract more FDI into the country. However, other countries are also providing incentives and as such the situation is becoming more competitive and difficult to attract FDI. The question now is, to attract the right kind of FDI since the labour intensive manufacturing sector is losing its competitiveness to low - wage countries in the region. This research has identified a number of significance that is outlined below:

1) FDI has contributed positively to Malaysia's economic development since mid 80s and as such it is vital for us to continue attracting such investment.
2) Discovering the factors influencing FDI in services is vital to further assist the government in policy formulation for the future.
3) The service sector contributes more than half of Malaysia's GDP and as such, is important for the government to further sustain its growth. Identification of the major factors influencing FDI in services is beneficial in the long run to further sustain and increase the sectors development.
4) Identification of new factors not known earlier can help Malaysia increase its competitive advantage

LITERATURE REVIEW

Theoretical Underpinnings behind ForeignDirect Investment

Why does a firm undertake FDI? Logically, an MNC is bound to incur additional transportation costs, face language and tax barriers and may face the risk of expropriation if it decides to move abroad. However, despite all these problems, MNCs are still rapidly crossing borders and expanding their businesses all over the world through FDI. Theoretically, the origins of FDI can be traced back by examining the work done by Vernon (1966), Kindleberger (1969), Hymer (1976), Knickerbocker(1973), Buckley and Casson (1976), Hennart (1982), Caves (1982) and Dunning (1977, 1980, 1981). Basically, the theories explaining FDI can be categorised into six groups.

Firstly, there is the imperfect market argument, which is based on transaction cost theory. This theory explains why MNCs should internalise their operations (Hymer 1976 & Hennart 1982). According to this theory, market imperfections arise due to barriers such as tariffs and foreign exchange controls that restrict the free flow of goods between nations. To avoid such barriers, it is better for MNCs to move abroad through FDI instead of exporting or licensing its products. Furthermore, the transaction costs of exporting or licensing is much higher since the MNCs may incur costs of search, costs of negotiation, costs related to enforcement of contract, transport cost and payment of taxes (Hill 2001). This justifies the reason for shifting production abroad.

Secondly, there is the product life cycle theory by Vernon (1966) which states that the production location for products moves from one country to another depending upon the stages of the product's life cycle. In other words, MNCs undertake FDI in other countries once demand there grows large enough to support local production and the domestic market is saturated and facing rising cost of labour. Hill (2001) argues that if this is the case, it still does not explain why MNCs use FDI and not exporting.

Thirdly, there is the ownership advantage theory where MNCs are fully exploiting certain intrinsic competitive advantage that the local firms may not have (Kindleberger 1969; Caves 1982; Buckley and Casson 1976, and Dunning 1977). These advantages refer to certain technological advantages including superior production techniques, better management methods, brand name, reputation, benefits of economies of scope and scale, monopolistic advantage and ownership of scarce resources (Hill 2001). These factors are also known firm specific advantages.

Fourthly, there is the locational advantage argument provided by Dunning (1977) that explains the nature and direction of FDI based on certain locational factors. MNCs carry out their FDI due to certain locational factors inherent in the host market. These locational factors are further divided into demand factors and supply factors (Coskun 2001). The demand factors are large market, high domestic demand, openness of the economy, potential growth etc while the supply factors are cheap and skilled labour, infrastructure quality, government incentives, logistic cost, access to technology etc. The Multimedia Super Corridor (MSC) in Malaysia is an example of an area with certain locational specific advantages since it attracts concentration of information and technological companies that conduct research. These factors are also known as country specific advantages.

Then, there is the 'follow the competitor' theory advocated by Knickerbocker (1973). According to this theory, FDI flows are a reflection of strategic rivalry between firms in the global marketplace. Knickerbocker (1973) examined the relationship between FDI and rivalry in the oligopolistic market structure and found that there is a tendency for firms to follow the leader. In the service sector, this is evident when service firms internalise as a reaction to competing firms actions (Li 1994). Engwall and Wallenstal (1988) in their investigation of Swedish banks found that there is a tendency for them to follow the leader when competing in a foreign market. However, this behaviour was also found to exist in the study of manufacturing firms (Flowers 1977). However, Hill (2001) argues that this theory still does not explain why the leader decides to go abroad through FDI rather than exporting.

'Follow the client' theory is another theory that gathered momentum in the 80s and tried to explain the expansion of service based MNCs (Contractor, Kundu & Chun Hsu 2002). According to this theory, advertising, financial services and market research companies tend to follow their multinational-manufacturing clients abroad (Erramilli 1990; Erramilli & Rao 1993; Winsted and Patterson 1998; Hellman 1996; Li 1994). It seems that from the 1980s onwards, knowledge based service sectors tended to expand internationally using the 'follow the client' theory when they followed their multinational clients abroad (Contractor, Kundu & Chun Hsu 2002).

The most comprehensive framework that was eventually developed and used extensively until today is Dunning's Eclectic Paradigm (Dunning 1979, 1980,). He integrated the ownership, internalisation and locational advantages or factors to form a single conceptual framework known as the OLI (Ownership, Locational and Internalisation advantage) paradigm. According to this paradigm, FDI will take place if the ownership, internalisation and locational advantages are realised together.

EMPIRICAL PERSPECTIVES - FACTORS INFLUENCING FOREIGN DIRECT INVESTMENT

This section reviews the empirical studies that examine the factors influencing FDI over the years.

Locational factors (Country specific factors)

Market Size/Attractiveness

Market size or market attractiveness can be assessed or measured by examining host country's GDP, population, growth of GDP, GDP per capita, etc. Empirical evidence investigating market size and attractiveness in the host country as a variable influencing FDI has shown mixed results although most findings support the theoretical view that large markets attract FDI (Knickerbocker 1973; Dunning 1973; Woodward & Rolfe 1993; Narula & Wakelin n.d.; Venkataramany n.d.; Anand & Kogut 1997). Ajami & Ricks (1981) in their study of FDI in the United States (US) found the 'extremely large US market' as the most important determinant of FDI into the US. Coskun (1996) in his 1994 survey on manufacturing firms in Turkey found 'promising Turkish market' as the most important determinant of inward FDI (cited in Coskun 2001, p.223).

In the internationalisation of hotels, the size and rate of growth of the tourism sector in the host country was found to be an important determinant of FDI in the travel business (Dunning & McQueen 1981). Recent investigation by Chandraprapalert (2000), Mbekeani (1999), and Erdal & Tatoglu (2001) also found market size a

very important determinant of FDI. They found the size of domestic market to be positively related to FDI inflow.

In the banking industry, similar results were found. Grouse & Goldberg (1991) found a positive relationship between levels of foreign investment in banking with the size of the local banking sector. This means that a sizeable local financial sector can help to sustain a greater number of local and foreign banks. This result corroborated the findings by Focarelli & Pozzolo (2001) who also found that expected host country economic growth and development of its financial system as vital determinants of FDI.

Galan & Benito (2001) in their research on the determinants of FDI in manufacturing and service companies in Spain found that growing demand in the host market and large size of the market as important determinants of FDI. Why does market attractiveness enhance inward FDI? One explanation given is that profit rates are higher in attractive markets (Ramchander, Reichert & Jayanti 1999).

Malaysia is one of the fastest growing economies in the South East Asian region after Singapore. The service sector's share of GDP in Malaysia is currently close to 57% (Business Times, Tuesday Feb 3 2004). Therefore, Malaysia has the potential to attract FDI into the services sector. Most service MNCs are commercially present and are not export oriented. They cater and serve the growing domestic market. Therefore, this factor is likely to enhance future growth of service MNCs. Market size is therefore likely to be an important determinant influencing FDI into the services sector, currently and in the near future.

Workforce factors

Workforce factors refer to variables such as cost of labour-wages, education level, skill level etc. Empirical evidences that investigated these variables found mixed results. For example, Globerman & Shapiro (1999), Jenkins & Thomas (2002), Narula & Wakelin (n.d) & Kravis & Lipsey (1989) found in their empirical investigation that wages are negatively associated with FDI. Coskun's (1996) study of FDI in Turkey and Galan and Benito (2001) found that labor cost is only a moderate factor. Schneider and Frey (1985) in their study of FDI found that skill-level is more important than labour cost. Bagchi-Sen (1995) and Dunning (1989) found that real wage factor is more important for service MNCs compared to manufacturing MNCs.

In the case of FDI into China, most studies showed that the cost of labour is a significant factor (Broadma & Sun 1997; Kerr & Peter 2001 & Zhang & Pu Yuk 1998). However, for the pharmaceutical industry, low cost of labour was found to be less important in a study of FDI in China in 1992 (Jiang, Christodoulou & Chingwei 2001). According to the researchers, this industry is highly technological and capital intensive and as such, the demand for cheap labour is not so important.

In the Malaysian scenario, some service industries such as banking, insurance, information technology, telecommunication and BPO are capital and knowledge intensive. These industries depend on semi-skilled and educated labour. Malaysia is able to supply such workforce at relatively lower cost compared to established service economies such as Singapore. That is why, this sector still attracts substantial amount of FDI. Furthermore, there may be other factors such as availability of high quality English speaking, educated work force which is highly important in the services sector. A report by Bernama (2004), said that Shell's success in Malaysia was largely due to the availability of cheap, highly talented, highly trainable and capable Information Technology (IT) workforce. However, in certain services sector, such as the hypermarket retailing business, cost of manual labour may be more relevant since this sector employs unskilled workforce. So, whether cost of labour is an important determinant may depend on the type of service industries under consideration

Theoretically, for services, the degree of interaction between customers and producers is normally high and as such the quality of the company's human resources becomes a critical or key factor in their ability to deliver the service (Cardone & Cazorla 2001). The services sector is also known to be idiosyncratic where it is associated with high levels of professional skills, specialised know-how and customization (Erramilli & Rao 1993). Therefore, the availability of qualified local personnel is an important factor for service MNCs compared to manufacturing MNCs. This view was also found by research conducted by Bagchi-Sen (1995), Dunning (1989) and Schneider & Frey (1985).

Mbekeani (1999) in his research on FDI in South Africa also found that MNCs are attracted to invest in countries with low-cost educated and skilled labour. In the insurance industry, Donghui (2001) found that quality of human resources is an important determinant in the supply of competitive insurance services. In the hotel industry, Dunning & McQueen (1981) also found that the availability of good hotel staff as important determinant for internationalisation of hotels.

However, Tatoglu & Glaister (1998) in their research on FDI in Turkey found that qualified local labor supply in the services sector was only a moderate determinant or factor as compared to the manufacturing sector. This view was also supported by Ioannatos (n.d) in his research on demand determinants of FDI.

Malaysia has managed to develop its labour force over the years into a highly educated and semi-skilled workforce. This augurs well for the knowledge-intensive services sector such as banking and insurance, since this sector employs highly skilled workers. The services sector tends to employ highly educated and skilled workers. The availability of such workers in Malaysia at a lower cost compared to our competitor such as Singapore should be a motivating factor influencing FDI into the services sector. However, this factor may not be important in certain services sector such as hypermarket retailing business which is labour intensive and employs mostly unskilled worker.

Government factors

Variables that will come under government factors are government incentives, economic policies, political environment and government promotions towards FDI.

Theoretically, the tax regime is expected to have an inverse relationship with FDI (Kerr & Peter 2001). In other words, lower taxes promote FDI and vice versa. The same goes with the openness of an economy. It was found that the more open an economy, the higher FDI it attracts (Kerr & Peter 2001). Brewer (1993), Woodward & Rolfe (1993), Kerr & Peter (2001), Tung & Cho (2000) and He & Guisinger (1993) found that tax incentives had a positive effect on FDI. The degree of openness was also found to have positive impact on FDI in many studies (Balasubramanyam, Salisu & Sapsford 1996; Kerr & Peter 2001). Kravis and Lipsey (1982) also found the degree of openness as measured by the high propensity to trade as an important factor influencing FDI. These findings were corroborated by Wilhelms (1998), who also found economic openness to have positive impact on FDI. She also found high corporate tax to be negatively correlated with FDI.

However, there exists empirical evidence that do not support the above results. For example, Lim (1983) found that tax incentives do not affect FDI. Similarly, Wint & Williams (2002) and Wells & Wint (1990) also found that promotions by governments had negative impact on FDI. A study of FDI in the pharmaceutical industry in China, also found government incentives as not important determinants of FDI (Jiang, Christodoulou & Ching Wei 2001). Winsted & Patterson (1998) in their empirical investigation in the services sector found that incentives by government were not important determinants to exporters. One reason behind this is that most countries in the same line of business may have similar promotions.

The political environment refers to the laws and regulations passed by governments that can affect viability of MNCs operations in the host country (Griffin & Pustay 1999). Experienced international businesses usually engage in political risk assessment to evaluate the political risks they face in a particular host country (Griffin & Pustay 1999). Moran (1983) stated that political instability is only a small part of the overall risks faced by MNCs (cited in Beamish, 2000, p.201). However, Ajami and Ricks (1981) and Nigh (1985), both found that political stability has a positive influence on FDI.

For the services sector, openness of the economy or deregulation of the services industry is highly important. According to Bagchi –Sen (1995) & Dunning (1989), deregulation and liberalisation of the services industry is important for the future growth of the financial and telecommunications industry. Li & Guisinger (1992) in their empirical study found service MNCs investments in developed countries to be positively related to the openness of the host country. Another research in the insurance industry found regulative barriers by host government as the stumbling block discouraging FDI (Geracimous 1987, cited in Zimmerman 1999). In Malaysia, deregulation of the services sector such as banking and insurance would certainly attract FDI by foreign financial institutions. Established large foreign financial institutions that have presence all over the world would certainly benefit from this liberalisation since it provides them with an opportunity to strengthen their market share. Similarly, this may also be the case for foreign hypermarket retailers that have already dominated the local market extensively.

The Malaysian government has provided numerous incentives to attract FDI over the years. However, most of our competitors have also provided similar incentives. Vietnam, Thailand, Indonesia and Philippines have been successful in pulling FDIs away from Malaysia and Singapore by coming up with similar incentive packages (Lim 2002). So, it is worth examining whether tax incentives and government policies are significant factors in attracting FDI.

Another important development in Malaysia is the establishment of the Multimedia Super Corridor (MSC) in 1995. In fact, Malaysia was the first country in the region to create the MSC. The MSC has attracted world class MNCs both in the services sector and manufacturing sectors. Numerous incentives such as tax exemptions, provision of government grants, etc were provided to attract foreign firms especially in the information

technology field to set up their offices in the MSC. This gave Malaysia an edge to attract FDI although other countries in the region are also creating their own MSCs. However, the success of the MSC is yet to be seen since the level of investment flowing into the MSC is not substantial enough (Ramasamy n.d.) Therefore, providing tax incentives alone may not be sufficient to attract FDI.

Where the Malaysian services sector is concern, certain industries are still highly regulated such as the telecommunication and financial industry. However, the financial sector is set to open up in the near future but full liberalisation is only targeted in 2007. There have been complaints from foreign investors that the incentives given by the government are mostly for the manufacturing sector in Malaysia. Other important parts in the supply chain such as support services are however, neglected (Business Times, 29 March 2004). In fact, many of these MNCs that are doing business here have their regional headquarters and design centres in Singapore (Business Times, 29 March 2004). Singapore is still somehow the preferred location by MNCs when deciding to establish regional headquarters within this region, although the cost of doing business there is much higher.

The availability of a large educated multi - lingual workforce in Malaysia is already a strong motivating factor attracting huge number of foreign call centres to establish their operations here (Idris 2003). According to the Asian Call Centre Industry Benchmark Study in 2003, Malaysia has about 575 call centres and is placed at par with Singapore, Thailand and Hong Kong (The Star, BizWeek 4 October 2003 p.27). According to the American Chambers of Commerce (2004), many foreign companies find that they can service markets from India all the way down to Australia and up to Japan from a centre located in Cyberjaya, Malaysia. These foreign companies find that Malaysians have deep industry experience, good research skills and wide exposure, which should be very attractive for service MNCs.

Infrastructure

The level of infrastructure in the host country refers to the quality of roads, railroad, dependable energy and telecommunication availability, credit and banking facilities and other financial, legal and transport systems (Wilhelms 1998; Griffin & Pustay 1999). Here again, empirical results on the influence of infrastructure on FDI brought mixed results. Wilhelms (1998) in her econometric study found that institutional factors such as commercial energy are positively correlated with FDI. Cheng & Kwan (2000) also found that quality of infrastructure as a very important factor influencing FDI in China.
In the services sector, the level of infrastructure development was found to be a more important determinant of FDI by service MNCs compared to manufacturing MNCs (Bagchi-Sen 1995; Dunning 1989). Root & Ahmed (1978) in their empirical investigation also found that effective services sector in terms of adequate infrastructure in the area of banking, finance, insurance, telecommunication, transportation and distribution had positive impact on the ability of the host country to attract FDI. Dunning & McQueen (1981) in their study of the internationalisation of hotels found that general infrastructure for tourism as an important factor influencing internationalisation of hotels. However, moderate support was found by Tatoglu & Glaister (1998) on the importance of infrastructure development for services compared to manufacturing

Malaysia has one of the most developed infrastructures in this region after Singapore. It has developed high quality infrastructure in the financial, telecommunication and transportation sector. An efficient and developed infrastructure can reduce cost of doing business not only in the services sector but also manufacturing sector. Therefore, good quality infrastructure is necessary to lure FDI.

Since this research is examining FDI in services, it will emphasise only on the variables that are deemed to be more important for service MNCs. As such, variables such as market size, workforce factors, infrastructure and government factors may be more relevant to the Malaysian services sector. A more detailed description will be provided in the conceptual framework section.

Ownership factors (Firm specific factors)

A MNCs ownership advantages can also influence FDI. As discussed earlier in the theoretical literature, MNCs owning a valuable asset that creates a competitive advantage in the home country can use that advantage to venture into markets abroad (Griffin & Pustay 1999). The ownership advantages that will be discussed in this section are experience effects, firm expertise, reputation/brand image and size of the firm.

Experience effects

Davidson (1980) had shown that American MNCs proceed abroad gradually, where initially they go to familiar markets that are close. As soon as they gain more experience, they move on to unfamiliar markets that are

geographically distant. Davidson (1980) showed that experience had a positive effect on FDI. In the service industries such as advertising, Weinstein (1977) also observed experience effects influencing FDI. As advertising MNCs grew in size and obtained more experience, they started to penetrate into Europe and Latin America. Erramilli (1991) found that as service MNCs obtained more experience, they tended to choose markets that are culturally less similar to home country.

However, Li (1994) also investigated experience effects in ten service industries and found that this is important only in the early stage of internationalisation. He found that the relationship between international experience and new service FDI in the Asia Pacific Region to be non – monotonic. In other words, the above proposition may be defeasible. Empirical research by Alon & McKee (1999) on the internationalisation of professional business services found a positive relationship between intention to internationalise and age of the firm. In other words, older and more experienced firms tend to internationalise faster. Even in the internationalisation of hotels, the 'experience effect' was observed (Dunning & McQueen 1981). They found that large hotels that are more diversified and experienced could enter new markets easily since they enjoy economies of scale and have vast managerial and organisational expertise.

Firm expertise

Schroath & Korth (1989) in their research on FDI in the insurance industry found that intellectual property right is an ownership advantage that needs to be protected when expanding abroad. Donghui (2001), in his empirical investigation also showed that technology is a key determinant of the supply of insurance services by MNCs. Galan & Benito (2001) in their research on Spanish financial companies found that they stressed the importance of specific and intangible assets such as technology, innovative capability and managerial expertise as their ownership advantage. However, they found that economies of scale do not influence FDI of Spanish financial institutions. Narula & Wakelin (n.d) found that technological assets of US MNCs have positive influence on FDI.

Reputation

According to Tatoglu & Glaister (1998), ownership-specific advantages applicable to manufacturing firms are also applicable to service firms. For service MNCs, reputation and brand image are very important and are key competitive advantages (Von Der Ruhr 2000). In the internationalisation of hotels, Dunning & McQueen (1981) also observed that well-known reputation and brand image can guarantee quality of hotel services if that particular hotel is well known for its quality.

Size of firm

Lastly, Grunbaugh (1987) and Culem (1988) in their studies of manufacturing industries found that large firms are more likely than small firms to be foreign investors. Firm size was also found to show positive impact on the internationalisation of banks and advertising firms (Ball & Tschoegl 1982; Terpstra & Yu 1988; Weinstein 1977).

In the case of the Malaysian services sector, variables such as reputation, experience effect, brand image, size of the firm are considered to be important for MNCs. For example in the banking industry, some of the foreign banks in Malaysia such as HSBC and Standard Chartered have been here for more then a century and also have presence all over the world. Their reputation, experience and size may definitely give them an edge over new players in the industry. However, this may not be true for new and small service MNCs. For example, for small and new MNCs in the call centre industry, it will take time for them to establish themselves internationally. However, they may have certain managerial expertise that others do not have which gives them an edge over their rivals.

Similarly, in the software industry the ownership advantage may be in the form of an intellectual property right or technology. Therefore, foreign IT companies located in the MSC may depend on their intellectual property right to create a niche in the local market On the other hand, in the hypermarket retailing business; most of the MNCs are still new and have been here for less than ten years. So, it is yet to be seen if they depend on certain ownership advantage such as size or reputation to venture abroad or it's more due to locational advantage such as attractive domestic market.

Following clients into overseas markets

According to studies on internationalisation of service firms, in the initial stage, they tend to follow their manufacturing clients when they move abroad (Erramilli 1990; Erramilli & Rao 1993 and Winstead & Patterson

1998). This was also found to be evident in the banking and insurance sectors (Hellman 1996 & Li 1994). In Finland, Cardone et.al (2003) observed that small banks were found to follow their clients as they move abroad. In Spain, the same study showed that Spanish banks moved abroad according to 'follow-the-client pattern'. 'Follow-the-client' pattern was also evident in the internationalisation of Finnish and Spanish insurance companies. Similar results were also found by Galan & Benito (2001) in their investigation of 103 Spanish companies.

Weinstein (1977) in his investigation of advertising MNCs, found that they also tended to follow clients already there and sometimes the clients are the ones who request them to follow them. This motive has also been observed in other international banking and advertising studies (Goldberg & Saunders 1980; Nigh, Cho & Krishnan 1986; Terpstra & Yu 1988 and Li & Guisinger 1992). According to Li (1994), service MNCs prefer to service their existing clients from their own country. Studies of Nordic financial service companies all over the world also found similar client-following pattern (Engwall & Wallenstal 1988; Majkgard & Sharma 1998 & Sharma & Johanson 1987).

It can be argued whether this follow-the-client theory holds for all service MNCs. In the retail trade sector such as the hypermarket retailing business, the existence of foreign players in the local market is to capture the domestic market. In this type of business, the service MNC is selling its products directly to local customers and not foreign manufacturers. Therefore, the foreign retailer's motive is more for market-seeking purpose. Even in the banking industry in Malaysia, some of the foreign banks such as HSBC and Standard Chartered have been here for more than a century. HSBC's entry into Malaysia can be traced back to the early 1900s. HSBC, which was then known as HongKong Bank, not only served its foreign clients but also became a major foreign bank domestically, servicing local businesses as well. It also became a banker to most Asian governments including Malaysia. Therefore, there is a possibility that service MNCs may only initially follow their foreign clients abroad. However, as the local market opportunities start to increase, these service MNCs may eventually seek local clients as well.

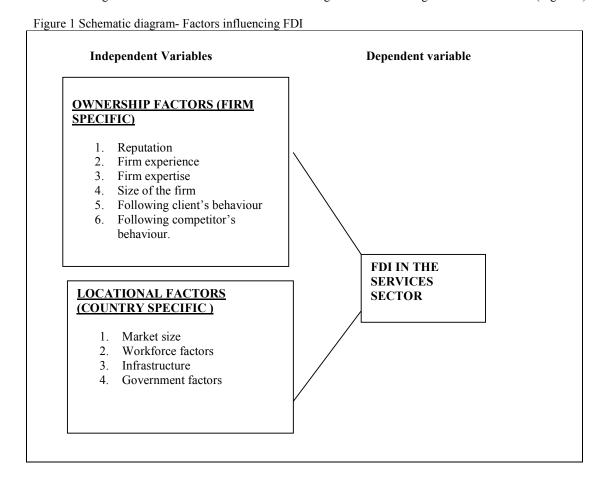
Following competitors overseas

This 'follow-the-leader' behaviour can be traced back to the work of Knickerbocker (1973), Flowers (1977) and Graham (1978) in their study of FDI by manufacturing firms. This was also evident in the internationalisation of advertising MNCs (Weinstein 1977). He found that advertising MNCs tended to go abroad as a defensive strategy to follow their competitors. This was later reconfirmed by Terpstra & Yu (1988). Hamel & Prahalad (1985) through their empirical investigation found that service MNCs undertook FDI to protect their international market position from attacks by major competitors.
A study of Swedish banks revealed that they tended to follow each other to the same foreign market, often choosing the similar entry mode (Engwall & Wallenstal 1988). Li (1994) found that service firms internationalise as a reaction to a competing service firm's strategy. In Finland, there were indications that insurance companies and small banks internationalised using 'follow-the-competitor' pattern (Cardone et.al 2003).

In the hypermarket retailing business in Malaysia, there is a sudden increase in the number of MNCs investing here. These hypermarket retailers fall under the oligopolistic market structure (Carlo 2002). Therefore, there may be some possibility that they may confirm to the follow-the-leader pattern of expansion. However, according to a report by Asia Pulse, the entry of these foreign retailers into Malaysia may be mainly due to our long-term growth prospect and large market size (Asia Pulse, March 17, 2001). As such, these retailers are merely seeking new markets for their expansion. In the case of the banking and insurance industry, for time being until 2007, the financial sector is still highly regulated. So, it is difficult to ascertain if the existing foreign banks are expanding according to follow-the-leader pattern since their expansion is strictly controlled by the government.

Therefore, it is also the aim of this research to find out whether the selected service MNCs being examined behave according to these two theories.

CONCEPTUAL FRAMEWORK

This section will describe the conceptual framework – research model and the proposed hypothesis that is developed to study factors influencing FDI in the Malaysian services sector.


Conceptual framework-research model

Dunning's Eclectic Paradigm will be the main model used in this research due to its comprehensiveness (Dunning 1980, 1993). This theory is one of the most comprehensive frameworks developed and used extensively until today (Dunning 1980). Dunning (1980) introduced the locational advantage to address the issue of why firms go abroad to a particular destination, which the internalisation theory ignores. His locational advantage (L) was then integrated with ownership (O) and internalisation advantage (I) to form a single conceptual framework known as the OLI paradigm. According to this paradigm, FDI will take place when the ownership, internalisation and locational advantages are all realised together.

However, only the locational and ownership factors will be considered. The internalisation factor is not considered since service MNCs are already internalising operations once they are commercially present in Malaysia. Internalisation will be considered if the research intends to compare between FDI and other modes of internationalisation such as licensing, franchising etc. Based on the review of the literature in the previous section, only those locational and ownership factors that are relevant to FDI in the services sector are selected.

Thus, the locational factors selected are market size, workforce factors, government factors and infrastructure. The ownership factors selected are firm experience, reputation, firm expertise, size of the firm, following client's behaviour and following competitor's behaviour.

These locational and ownership factors will thus be the independent variables in this research. FDI in services is the main variable of interest in this study and is therefore the dependant variable. The relationship between the dependant variable, FDI, will therefore be explained by the independent variables described above. The schematic diagram of the theoretical framework examining factors influencing FDI is shown below (Figure 1).

Figure 1 Schematic diagram- Factors influencing FDI

HYPOTHESES DEVELOPMENT

Hypotheses are developed to examine the factors influencing FDI in the services sector. The locational factors selected in this research are basically country specific factors. Market size is likely to be an important factor

influencing most service sectors such as banking and insurance, retailing, transportation, telecommunication due to the positive outlook of the Malaysian economy over the years and in the future.

The availability of high quality workforce is also expected to influence FDI in certain services sector such as banking and insurance and call centre industries. A number of call centres have established their operations here in Malaysia due to this (Idris 2003). Availability of low-cost educated workforce is vital for the services sector since the degree of interaction between customers and producers is normally high. As such the quality of human resources becomes a critical or key factor in the ability of MNCs to deliver the services. A report in Bernama (2004), mentioned that availability of cheap and highly talented and trainable workforce is a key factor, why many foreign service firms are locating their base here. Many MNCs in the call centre industry are also establishing their Operational Headquarters (OHQs) in Malaysia (Business Times 26 Dec 2002).

Infrastructure is the third variable that is selected since it is deemed to be highly important in creating an efficient services sector. This is important for attracting FDI into sectors such as banking and insurance, transportation, telecommunication etc.

Government support is the fourth locational factor selected in this study. The Malaysian government has provided numerous incentives and developed positive economic policies to attract FDI over the years. However, the services sector is still highly regulated but is expected to further liberalise in the near future. Therefore, in the short run, the highly regulated services sector is discouraging FDI. In the case of tax incentives, numerous tax incentives in the form of tax relief and exemptions have been given to further attract foreign firms to establish their operations at the MSC. This factor is therefore, deemed to be important to attract FDI. In the line of this discussion, we therefore formulate the following hypothesis:

H1: There is positive relationship between market size and FDI in services
H2: There is positive relationship between workforce factors and FDI in services.
H3: There is positive relationship between infrastructure and FDI in services.
H4: There is positive relationship between government support and FDI in services

As for the ownership factors, one of the most important factor influencing FDI in services is brand image and reputation (Tatoglu & Glaister 1998; Von Der Ruhr 2000). The Malaysian services sector has attracted numerous well known service MNCs in various industries. Some examples include HSBC, Citi Bank, Standard Chartered, Allianz, DHL, Federal Express, TNT, etc. The ownership of well respected brand name and reputation is therefore expected to influence these MNCs to continue to expand internationally through FDI.

The second and third ownership factors influencing FDI in services are the size of the firm and firm experience. Large MNCs are more likely to have stronger competitive edge due to its ability to enjoy greater economies of scale. In the banking, insurance and transportation industries, it is common to see large MNCs in the services industry having presence all over the world. Service MNCs that have more experience are normally at a higher point of the learning curve, giving them more confidence to venture abroad. In the line of this discussion, the following hypotheses are elicited:

H5: There is positive relationship between firm's reputation and FDI in services.
H6: There is positive relationship between firm's experience and FDI in services.
H7: There is positive relationship between size of the firm and FDI in services.

Another important variable selected that is deemed to be important for service MNCs is firm expertise such as ownership of intellectual property right. This is normally a vital ownership advantage for information technology companies that develop software. These MNCs are likely to expand internationally through FDI to protect the ownership of their intellectual property right.

Other firm expertises are ownership of managerial, marketing and technological knowledge. Lately, Malaysia has become an attractive regional outsourcing hub for many service MNCs especially in the financial and telecommunication sector. Many of these service MNCs are likely to rely on their managerial, marketing and technological knowledge to remain competitive. Even, the foreign financial service firms use this ownership advantage to stay ahead internationally. Therefore, ownership of such factors can motivate foreign service firms to expand abroad.

FDI in Malaysia can be also explained by follow-the-client and follow-the leader (competitor) behaviour. Follow-the-client strategy has been a major motive of service MNCs to venture abroad and has been observed in the banking, insurance and advertising industry (Hellman 1996; Li 1994; Cardone et al. 2003; Galan & Benito 2001; Weinstein 1977; Goldberg & Saunders 1980; Nigh, Cho & Krishnan 1986; Terpstra & Yu 1988; Li &

Guisinger 1992)). Therefore, it is expected that FDI by service MNCs in Malaysia is also influenced by the existence of their home country clients here.

The follow-the-leader or oligopolistic reaction theory has been used to explain the behaviour or motive of service MNCs in 10 service industries such as insurance, reinsurance, securities, trading and retailing, accounting and advertising, construction, publishing and airlines (Li 1994). This pattern has also been observed by service MNCs in the advertising industry (Terpstra and Yu 1988). Therefore, it is expected that FDI by service MNCs in certain service industries in Malaysia that show oligopolistic characteristics, may follow this pattern. This leads us to the following hypotheses:

H8: There is positive relationship between firm expertise and FDI in services.
H9: FDI by selected service MNCs in Malaysia is likely to confirm to the follow-the- client behaviour
H10: FDI by selected service MNCs in Malaysia is likely to confirm to the follow-the- competitor behaviour

CONTRIBUTION OF THIS STUDY

This research is very unique in its own sense. It is investigating FDI in the services sector, an area where there is lack of research due to difficulties in obtaining secondary data. Most research on FDI tends to use secondary data and therefore is relying extensively on economic data such as Gross Domestic Product, Interest rates, Inflation rates etc. This research uses primary data and as such is able to collect and include a larger number of variables. It is also able to include certain variables that are difficult to quantify and not easily available such as reputation and multilingual and people skills (under workforce factors). This research intends to contribute enormously to the literature on FDI in services by uncovering and exploring in greater depth old and new variables.

Providing tax incentives and promotions may not be sufficient to attract FDI into the service sector. This is because other countries can provide similar tax packages and incentives Workforce factors such as availability of skill workforce, cost of labour and education level have been identified as highly important to attract FDI in previous research. However, this research has included new items such as multilingual workforce, people skills, multicultural workforce, English speaking low-cost educated workforce which may be more relevant to a country like Malaysia. In the services sector, there is a tendency to employ educated workforce and therefore cost of educated workforce may be a relevant factor. According to AT Kearney's Offshore Location Attractiveness Index 2004, Malaysia is placed third on the list for top outsourcing destinations for call centre services (The Edge Daily, 25th August 2004). This means that we are ahead of Singapore and other neighbouring countries in this region. So, the Malaysian workforce's unique characteristics are expected to be important determinants of attracting FDI into the services sector.

Similarly, the government factors do not only look at standard variables such as government policies, tax incentives etc. This research has included new items under government factors that are deemed to be more important such as transparency, special agencies to handle FDI, incentives to expatriate personnel, tax exemptions to service MNCs and new regulatory environment for service MNCs This research has also included reputation as an important factor influencing FDI into the services sector. It has been mentioned in the literature that reputation is a more important factor for service MNCs (Von Der Ruhr 2000).

The services sector itself is very unique due to its idiosyncratic characteristics (Boddewyn et.al 1986). As such service MNCs may have certain intangible characteristics and expertise that may be different. Due to this, these service MNCs may be able to differentiate and enhance their ownership advantage. This gives greater reason to further uncover such uniqueness.

The infrastructure factor has also included new items that are deemed to be more important to service MNCs in Malaysia. Apart from the standard infrastructure facilities that most governments create, Malaysia has developed special economic locations and created intelligent cities such as the MSC to further attract MNCs especially those in the ICT field. Those MNCs that are located in this economic zone are further provided with additional incentives.

The findings from this research will contribute to effective policy formulation. There is a need for the government to identify the motivational factors inducing service MNCs to invest in Malaysia. By doing so, the government can then introduce new incentives for attracting FDI into the service sector. Apart from general FDI incentives and promotions, there may be a need to introduce specific FDI incentives and promotions solely for the services sector. Even in the services industry, there may be a need to further introduce specific incentives for the different categories in the service sector.

Finally, the findings from this research can contribute further to the development of FDI theories in services, an area where research is currently lagging behind practice.

ABSTRACT

This study estimates the Asai (1999) proposed simplified BMR model (Ball *et al*., 1988) and ARY model (Akerlof *et al*., 1988) using quarterly data from Malaysia, Thailand, Japan and US. Unlike other earlier authors, we ensure that our models' residuals are free from serial correlation and ARCH effects. For the ARY model, all countries under study show strong evidence for new Keynesian model, with the exception of Japan, which produces inconclusive results. As for the BMR model, all countries provide strong evidence for new Keynesian model. Our finding implies that government generally plays a significant role in altering the economy's business cycle.

INTRODUCTION

Macroeconomists have long been debating on the issue of whether allowing the economy to operate freely under market force will be more successful in achieving macroeconomic goals than otherwise. Most related studies are conducted based on the new classical and new Keynesian hypotheses.

In the new classical hypothesis, market force functions well and government intervention should not exist because it is believed that: (a) inflation is more costly than unemployment; (b) short-run Phillips curve is quite steep; the economy's self-correcting mechanisms work smoothly and quickly. The new Keynesians, on the other hand, do not believe in market force and they argue that government intervention is important because: (a) unemployment is more costly than inflation; (b) short-run Philips curve is rather flat; (c) the economy's self-correcting mechanism is slow and unreliable.

The new classical economies and the real business cycle theory are based on the dual assumptions of rational expectations and continual market clearing. As a result, according to these theories, unemployment is voluntary, and anticipated money shocks have no real effects. Akerlof *et al*. (1988) comment that unlike the new classical theory, new Keynesian economics fits most important stylized facts of the business cycle: that cyclical unemployment is largely involuntary and that anticipated demand shocks do affect real output. To this end, empirical evidences suggest that no one hypothesis can dominate the other and the rally is still going on.

This paper attempts to provide empirical evidence on a new Keynesian theory of the output-inflation trade-off using the Asai (1999) proposed simplified versions of BMR model (Ball *et al*., 1988) and ARY model (Akerlof *et al*., 1988). Briefly, the interpretation of these two models is based solely on the *t*-statistics of the estimated coefficients. We note here that *t*-statistics are not relevance if the model's residuals exhibit autocorrelation or heteroscedasticity. However, from our literature survey, most of the earlier authors either do not do residuals tests or assuming at the outset the absence of serial correlation or ARCH effects (see example, Asai, 1999; Katsimbris and Miller, 1996; Ball *et al*., 1988 and Akerlof *et al*., 1988). Thus, the contribution of this paper to the current literature is to provide more reliable empirical evidence from models that are free from autocorrelation or heteroscedasticity effects. Specifically, unlike earlier papers, this study first conduct residuals diagnostic tests before proceed to the formal model estimation using non-linear least square method.

The rest of this paper is organised as follows: Section 2 reviews the related studies. This is followed by a description of the methodology used in this study. Section 4 presents the empirical results as well as the analysis of the findings. Finally, concluding remarks are given at the end of the paper.

REVIEWS ON RELATED STUDIES

The work of Lucas (1973) was the first to provide empirical evidence to the new classical hypothesis. Lucas (1973) model assumes that economy has a basic rational, maximizing firms and individuals, and that the market always clear. Lucas (1973) finds that there is a negative correlation between the output-inflation trade-off parameter and the variances of both nominal aggregate demand and the rate of inflation.

In an attempt to challenge the existing tests of the new classical model, Ball *et al*. (1998) develop a dynamic new Keynesian model to analyse the effects of menu costs on price adjustment. The model assumes an imperfectly competitive market in which firms control their own prices, subject to menu cost, with the objective of profit maximizing. It was believed that the real effects of a nominal shock depend on how often firms adjust their prices. The greater the speed of adjustment of individual prices, the smaller the real effects of a nominal shock, and thus the steeper the Phillips curve. The frequency of price adjustments depends on the variance of aggregate demand and the inflation rate. In particular, the higher the variance of aggregate demand, the more uncertain the firm's future optimal price is, and the shorter the firm's time interval between price changes. A negative correlation thus exits between the variance of aggregate demand and output-inflation trade-off, and between average rate of inflation and the output-inflation trade-off.

Ball *et al*. (1988) used a two-step procedure, employing a sample of 43 countries with annual data to: (1) estimate the standard Lucas aggregate supply curve by regressing real output on its own lagged value, the rate of change of nominal GNP, and a time trend over the 1948–86 period; (2) estimate cross-country linear and non-linear specifications of the estimated output-inflation trade-off coefficients (τ) on the average inflation rate and the variability of aggregate demand and/or the variability of the inflation rate; and (3) estimate time-series cross-section equations by regressing the change in the output-inflation trade-off coefficients between two sub-periods (i.e. 1948–72 and 1973–86) on the respective changes of the average rate of inflation and demand variability. Their results support a negative correlation between short-run output-inflation trade-off and the average inflation rate. Ball *et al*. (1988) conclude that strong evidence exists for new Keynesian model and, by implication, against the new classical model.

Akerlof *et al*. (1988), however, argue that given that average inflation rate and the variability of nominal GNP are highly correlated (correlation = 0.92), the test of Ball *et al*. (1988) is inevitably a weak test of their theory against the new classical theory, as well as other new Keynesian alternatives. They further argue that expected inflation and the volatility of nominal GNP growth have probably not been constant as assumed by Ball *et al*. (1988) in most countries in reality. As such the optimal interval between price changes would also have changed in each country over time. Consequently, the output-inflation trade-off coefficient (τ_t) must be allowed to vary over time. Akerlof *et al*. (1988) perform the same cross-country test employing a different non-linear specification (i.e. the inverse of trade-off coefficient) and find no evidence supporting the new Keynesian hypothesis. They conclude that aggregate data just do not seem to discriminate between the hypothesis of interest and very different alternatives.

Katsimbris and Miller (1996) re-examine the tests proposed by Ball *et al*. (1988) and Akerlof *et al*. (1988) using both pooled and country-by-country regressions. Their results show that autocorrelation could possibly lead to misspecification and thereby lead to conclusion in favour of the new Keynesian model. They find no evidence to support the new Keynesian hypothesis with the pooled data (39 countries altogether). Meanwhile, on a country-by-country basis, little evidence exists that is consistent with either the new Keynesian or the new classical models.

Asai (1999) also reconsider the empirical tests of Ball *et al*. (1988) and Akerlof *et al*. (1988) and they propose a simple and straightforward testing procedure for each model. They take into account of a unit root in real output and modelled time varying variance of inflation rate using generalized autoregressive conditional heteroscedasticity (GARCH) models. Their results for Canada, France, Germany, Italy, Japan and the US support the new Keynesian hypothesis.

METHODOLOGY

In this section, we provide a brief description of the methodology used in this study, which includes the Asai (1999) proposed models as well as the sample data.

The Model

We mirror the Asai (1999) proposed testing procedure to estimate our models, with minor deviations. After taking account for the existence of unit roots, Asai (1999) proposes to estimate the Lucas function by

$$y_t = \alpha + \tau_t \Delta x_t + \sum_{i=1}^{p+m} \lambda_i y_{t-i} + \gamma t + \mu_t, \, t = 1, \dots, T \tag{1}$$

where y is the log of real GDP, x is the log of nominal GDP, τ is the time varying trade-off coefficient, Δ denotes the differencing operator, p denotes the lag length, of which coefficient is significant, m is the number of unit roots in y (equivalently the order of integration), and T is the sample size.

According to Ball *et al*. (1988), the trade-off coefficient is related to inflation rate in the following manner:

$$\tau_t = a_1 + b_1 \pi_t + c_1 \sigma_t \tag{2}$$

where τ_t is the trade-off coefficient, π_t is the inflation rate and σ_t is the time-varying standard deviation of inflation.

In contrary, Akerlof *et al*. (1988) used the functional form

$$\frac{1}{\tau_t} = a_2 + b_2 \pi_t + c_2 \sigma_t \tag{3}$$

in place of Equation (2).

Thus the Asai's (1999) version of BMR model is

$$y_t = \alpha + (a_1 + b_1 \pi_t + c_1 \sigma_t) \Delta x_t + \sum_{i=1}^{p+m} \lambda_i y_{t-i} + \gamma t + \mu_t, \, t = 1, \dots, T \tag{4}$$

Following Katsimbris and Miller (1996) and Asai (1999), we assume that a significantly negative coefficient on the inflation term supports the new Keynesian model and that a significantly negative coefficient on the time varying standard deviation of inflation and insignificant negative coefficient of inflation support the new classical model.

Asai's (1999) version of ARY model is

$$y_t = \alpha + \frac{\Delta x_t}{a_2 + b_2 \pi_t + c_2 \sigma_t} + \sum_{i=1}^{p+m} \lambda_i y_{t-i} + \gamma t + \mu_t, \, t = 1, \dots, T \tag{5}$$

By the same token, we assume that a significantly positive coefficient on the inflation term supports the new Keynesian model and that a significantly positive coefficient on the time varying standard deviation of inflation and an insignificant positive coefficient of inflation support the new classical model.

In this study, we estimate equation (4) and equation (5) using quarterly observations of GDP, inflation rate and time varying standard deviation of inflation for Malaysia, Thailand, Japan and the US. Our estimation procedure deviates from that of Asai (1999) in the sense that we do not use GARCH to model σ_t. Nevertheless we do diagnostic tests to check whether our model's residuals are free of serial correlation and ARCH effect up to 4 lag-lengths. We include GARCH (1,1) effect test to check higher order ARCH effect. While it is known that Katsimbris and Miller (1996) and Asai (1999) adjusted for autocorrelation and GARCH effect respectively in modelling σ_t, it is unclear whether they have performed residuals diagnostic tests. Thus, one may query the viability of their results.

The Data

In this study, we estimate equation (4) and equation (5) using quarterly observations of nominal and real GDP, inflation rate and time varying standard deviation of inflation for Malaysia, Thailand, Japan and the US. All data are collected from International Monetary Fund's International Financial Statistics (IMF/IFS). As these observations are not all readily for use, we have to construct them.

Quarterly nominal GDP is constructed from first regressing the annual nominal GDP with annual money supply (M_3) and then substituting the quarterly money supply to the regression model to interpolate the needed GDP. The fourth quarter's values are set equal to the observed annual data (Bahmani-Oskooee, 1986). As the R^2 values of regression are around 99%, we assume that our estimated quarterly GDP are good enough to reflect the actual observations. Real GDP are obtained by deflating the nominal GDP with the CPI. Inflation rate is calculated from the CPI series using the standard definition. Time varying standard deviation is obtained by computing the standard deviation of the inflation rate taking into account of time factor. Upon transformations, our ultimate usable data starts from 1980:1 and ends at 2000:4.

RESULTS AND ANALYSIS

Before we proceed to the formal model estimation, we provide some statistical properties of the time series data used in this study. The logarithmic transformed nominal and real GDP series are first subjected to unit root test using the Phillips-Perron (PP) test. These results are summarised in Table 1. All series are stationary after first differencing, indicating that $m = 1$ for all countries.

Table 1: Unit Root Tests

Country	lag	y	lag	Δy	lag	x	lag	Δx
Malaysia	1	−2.574	1	−9.796*	1	−1.868	1	−9.523*
Thailand	4	−2.144	4	−9.783*	4	−2.144	3	−9.783*
Japan	1	0.287	1	−11.287*	1	1.292	3	−8.080*
US	4	−2.493	1	−8.234*	1	−2.494	4	−6.737*

Notes: * denotes significant at 1%.

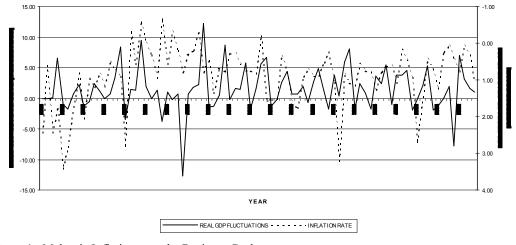
The inflation over the business cycle for all countries is plotted in Figures 1 to 4. It is obvious from the figures that for most of the time real growth rate and inflation rate are negatively correlated.


Figure 1: Malaysia Inflation over the Business Cycle
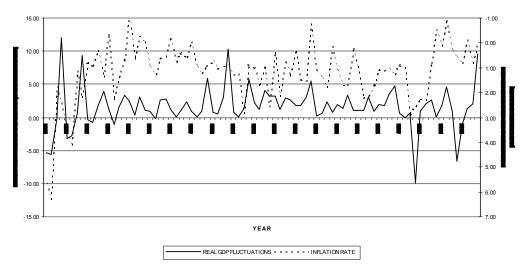

Figure 2: Thailand Inflation over the Business Cycle
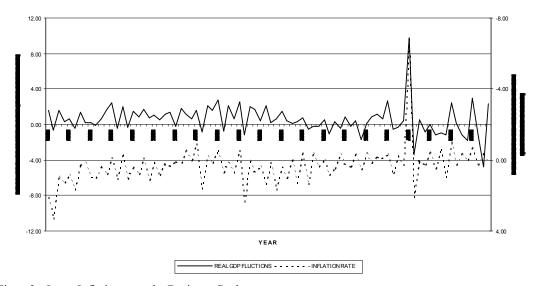

Figure3: Japan Inflation over the Business Cycle
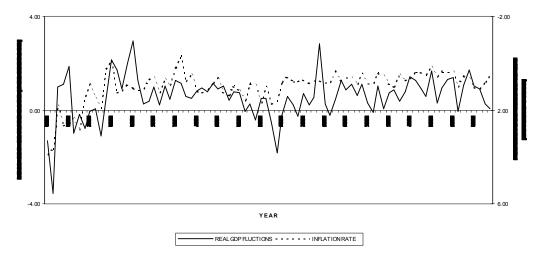

Figure 4: US Inflation over the Business Cycle

We then use the non-linear least square method in RATS program to estimate equation (4) and equation (5) and the results of estimation are reported in Table 2 and Table 3 respectively. For BMR model, all countries support the new Keynesian hypothesis. For ARY model, Malaysia, Thailand and US are supportive of new Keynesian hypothesis, whereas Japan shows inclusive results. The Lagrange Multiplier test for serial autocorrelation shows that all residuals are free from serial correlation problem up to 4 lag-lengths. Meanwhile the Lagrange Multiplier test for ARCH effect fails to detect any ARCH effect in all the residuals up to 4 lag-lengths or higher order. Since our results are obtained from models that are free from any autocorrelation or heteroscedasticity effects, our finding is more persuasive than previous studies.

Table 2: Results of BMR Model

Country	Lag[a] m	p	Estimated Coefficient[b] b_1	c_1	Diagnostic Test[c] LM (4)	ARCH (4)	GARCH (1,1)	R^2
Malaysia	1	1	−8.615 (−4.85)*	−0.717 (−0.06)	7.651 [0.11]	0.771 [0.94]	0.040 [0.98]	0.9997
Thailand	1	1	−15.439 (−5.80)*	9.542 (−1.63)	5.714 [0.22]	1.270 [0.87]	0.025 [0.99]	0.9998
Japan	1	1	−46.153 (−17.68)*	−32.862 (−1.86)	4.564 [0.38]	2.939 [0.57]	0.002 [0.99]	0.9993
US	1	1	−33.533 (−11.25)*	11.737 (0.80)	4.361 [0.36]	2.862 [0.58]	0.694 [0.71]	0.9997

Notes: [a] p is chosen such that no serial correlation remains in the residuals. [b] Coefficients as defined in Equation (4). t–statistic is given in parenthesis. * denotes significant at 5% or better. [c] Marginal significance value is given in square brackets.

Table 3: Results of ARY Model

Country	Lag[a] m	p	Estimated Coefficient[b] b_2	c_2	Diagnostic Test[c] LM (4)	ARCH (4)	GARCH (1,1)	R^2
Malaysia	1	2	6.124 (3.26)*	−4.531 (−0.31)	5.975 [0.20]	4.311 [0.37]	0.510 [0.77]	0.9997
Thailand	1	1	18.446 (8.86)*	−19.543 (−3.26)*	7.605 [0.11]	1.254 [0.87]	0.009 [0.99]	0.9998
Japan	1	3	14.333 (8.65)*	88.961 (2.51)*	3.701 [0.45]	2.256 [0.68]	0.017 [0.99]	0.9990
US	1	7	46.649 (12.14)*	10.695 (0.78)	5.020 [0.29]	3.166 [0.53]	0.521 [0.77]	0.9998

Notes: [a] p is chosen such that no serial correlation remains in the residuals. [b] Coefficients as defined in Equation (5). t–statistic is given in parentheses. * denotes significant at 5% or better. [c] Marginal significance value is given in square brackets.

CONCLUSIONS

We estimated the Asai (1999) proposed simplified BMR model and ARY model using quarterly data from Malaysia, Thailand, Japan and US. We take into the account of serial correlation and ARCH effect in the residuals terms. For the ARY model, Malaysia, Thailand and US show strong evidence for new Keynesian model, while Japan produces inconclusive results. As for the BMR model, all countries provide strong evidence for new Keynesian model. This finding implies that government generally plays a significant role in altering the economy business cycle. This is not surprising as most countries do manipulate their macroeconomics variables in order to maintain economic growth in certain range.

ABSTRACT

Malaysia can be regarded as one of the main economy in South East Asia apart from Singapore in terms of trade and tourism. With the awareness that Malaysian government has on tourism over the years, this paper will seek to investigate the relationship between trade and tourism that might evolve in the process of development by using cointegration and causality tests. The research is conducted with quarterly data from 1981 to 2001 on international trade and tourism flows between Malaysia and it major trading partners namely ASEAN, Japan and United States. The results differ across countries and provide a strong support for a systematic relationship between tourism and trade and causality run both ways. The results provide an important implication for decision making on Malaysia's policy with regard to trade and tourism. This policy should specialize on both business and holiday/pleasure travel concentrating on recreational resorts and eco-tourism.

INTRODUCTION

Tourism is the composite product that enters into international trade flows as an invisible export item. It differs from other commodity exports in the sense that the consumer or the tourist has to consume the product in the exporting country. It usually faces fewer trading restrictions than other exports. Moreover, it has been argued that tourism generates more pecuniary as well as non-pecuniary benefits and costs than other export industries. Does travel industry follows the dictates of international trade theories? For example, the popular version of the 'Theory of Comparative Advantage' suggests that the differences in relative factor endowments serve as the main basis for international trade and a nation will have a comparative advantage in producing those goods or services in which it is abundantly endowed. Applying the theory, the countries that possess an abundance of underutilised labour and natural resources are likely to have a comparative advantage in exporting tourism services. While it applies to some countries (such as Indonesia, Thailand, and Carribean Islands), there are many exceptions. For example, tourism is a major industry in USA and Canada, a country that does not have cheap labour. Also in United Kingdom neither has abundant natural resources nor cheap labour, yet it is popular tourist destination. Malaysia, on the other hand, a nation characterized by labour abundance and virtually many natural resources available and still emerges as a premier tourist destination in South East Asia.

Comparative advantage is dynamic and changes over time as suggested by the well-known 'Product Cycle' theory. The concept has found numerous applications in tourism as experts studied the progression of a tourist attraction especially in resorts by applying stage-theoretic framework (for example, 'Tourist Area Life Cycle' theory). In an article by Toh, Khan and Ai-Jin Koh (2001), they proposed a new trade theoretic approach to study the relationship between the development stage of a country and the state of its tourism industry. The postulation is that less-developed countries would generally be closer to an 'introductory stage' or net exporters of tourism and the developed countries would be closer to a 'decline stage' or the net importers of tourism based on the travel balance which is define as net of travel exports over imports. While the prediction of the model is yet to be substantiated with data for larger number of countries, Toh, Khan and Ai-Jin Koh (2001) apply a different investigative technique to study the relationship between international trade and tourism.

Intuitively, one can argue that as a country makes economic advancement, most of its macroeconomics aggregates move upward and the movement of different variables such as merchandise trade and tourism services over time can perhaps establish more kind of a pattern or causality. Countries with higher trading volume are also likely to be more open economies and thereby leading a more developed tourism industries which accounts for a greater percentage of the country's GDP. Larger travel industry also leads to expansion of trade as the requirements for tourist commodities increase overall trade flows. At the same time, as friendship between countries evolves through trading of various goods and services, travel becomes more widespread. Kuledran and Wilson (2000) tried to investigate the trade-tourism nexus econometrically by using Australian data for her travel and tourism partner and it is the only published study in this area of tourism until date.

How can tourism influence international trade? If we concentrate on business travel alone (i.e. visitors who travel mainly for business purposes), the idea is pretty straightforward. Business visitors travel to a country for the purpose of buying certain products from that country for the purpose of buying certain products from that country or selling certain products to that country. Successful business trips therefore directly create a flow of exports and/or imports in subsequent periods. Such visits may also create a lot of positive externalities or indirect effect on both trade and tourism. Increased business travel may motivate others particularly friends and relatives of those who are involved in business to take holiday or pleasure trips to those destinations either alone or accompanied by business friends. Moreover, growing business transactions and dealings create interest among consumers about the products as well as source countries and these may subsequently lead to a surge in the flow of business/holiday visits to those countries.

Can other visitors apart from business visitors influence trade as well? The answer is 'YES'. International visitors, whether they go for visiting friend or relatives, studying overseas, medical treatment or purely for pleasure or holidaying, may identify business opportunities that could lead to either export sales or import purchases in subsequent period. Moreover, tourist may demand or consume certain types of products that are not produced in that country and therefore have to be imported and thus leading to a surge in import requirements for that that country. In open economies such as Malaysia and Singapore, tourists spend substantially on imported goods and services and thus contribute to import flows as well as total trade, though technically speaking, these constitute an outflow of tourist spending (import leakage) in those countries.

TOURISM IN MALAYSIA

Tourism is one of the fastest growing industries in Malaysia. Growing at average annual rate of 30% per in the past two decades, visitors arrival reached a record high 6.5 million in 1995. Double-digit growths were recorded in the early 1990's due to the aggressive advertisement by the Malaysian Tourism Board (MTB). However, the rise in visitor arrivals became relatively slower in the late 1990's. The visitation rate suffered major setbacks in 1991 where it rose by a mere 2.1% due to Gulf War and the worst disaster came in 1997 and 1998 where arrival rate declined by almost 8.9% and 20.5% when the region was hit by an Asian Crisis which crippled the whole region economically. It is however heartening to see that the tourism industry recovered very quickly and by the year 2001, the visitor arrivals again exceeded 5 million. Then came September 11 incident where tourist arrival especially from Europe and the United States decline dramatically and but it has been compensated with an increase of 32.2% tourist from Middle East and thus Malaysia does not suffer as much as in other countries in the region. It is due to the tough stance by the Malaysia Government against any form of terrorism.

Tourist is Malaysia are predominantly drawn from Asia especially from Middle East and the ASEAN especially from Singapore, Thailand, Indonesia and Brunei which represents the top tourist market that has been supplying more than 50% of total visitors to Malaysia. Other major tourist market for Malaysia includes Japan, Australia, Taiwan, UK, USA, China and India. Most of the tourist that came here are mainly for pleasure since Malaysia has a sufficient fund of natural attractions and recreational facilities. The so-called pure holidaymakers constitute the bulk of tourists coming to Malaysia which is nearly 60% of the total arrival. The proportion of business travellers currently hovers around 15% of the total tourist arrival in Malaysia.

Tourism contributes more than RM 9.2 billion to Malaysia's economy, accounting for roughly 25% of total GDP which includes tourism's multiplier effects on other sectors. In the balance of payments accounts, the size of the travel balance has been growing over the years although the rate growth has slowed down in the early 1990's when the travel industry seemingly matured. Travel credit or receipts earned from foreign visitors was RM 12,321.3 million in 1996 and rose to RM 21,291.1 million in 1997. But it has been badly affected by the economics crisis evident by a sharp fall in the travel receipts in 1997 and 1998 but still managed to record a good receipts in 2002 and 2003. Travel debit, or expenditure of domestic residents overseas, sees the same trend as for travel credits. Most of the Malaysian during the crisis prefers to stay inside the country rather than to take vacation abroad, mostly due the fact of higher depreciation of Ringgit. But nevertheless, the overall trade balance is increasing overtime since most of the Malaysian prefers to travel domestically rather than overseas.

Malaysia is an open economy and the reliance on trade and its importance in generating income can be seen from its increasing ratios of import per GDP and export per GDP over the years. The former was around 40% in the 1960 but it shoots up to more than 200% in the 1980 before settling around 150% in early 1990s. Currently, it hovers around 100% mostly due to the economics crisis in 1997 and 1999, but it gradually stabilising to 150% marks in 2003. The latter was also above 100% throughout year and it currently stood at 103%. Total trade of Malaysia in 2003 was more than 150% of its real GDP and the country's major trading partners included countries such as USA, Singapore, Japan, Hong Kong, Indonesia, Thailand, Taiwan, UK and Australia. Not unlike tourist arrivals and receipts, exports and imports figures also suffered setbacks in the mid-1980s due to economics depression, Gulf War in 1991 and Asian financial crisis in 1997-1998. The rebound in trade after

each fall was however quite swift and strong due to capital control measures adopted by the government. The overall pattern displayed by trade and tourism data provides some support for a long-term relationship between the two but such relationship can only be established by undertaking appropriate econometric studies.

METHODS AND DATA

This paper seeks to investigate the long-term relationship between international trade and tourism flows between Malaysia and its major trade and tourism partner. A battery of cointegration and causality test are used to analyse bilaterally the trade and tourism data for Malaysia and her partners, namely ASEAN, Japan, Australia, UK and USA. First, Unit Root tests are conducted to verify the stationarity properties of the time series with the absence of trend and long-run mean reversion as to avoid spurious regressions. A series of is said to be integrated of order *d*, denoted by I(*d*), if it has to be differenced *d* times before it becomes stationary. If a series, by itself, is stationary in levels without having to be first differenced, then it is said to be I(0). A standard Dickey-Fuller (DF), Augmented Dickey-Fuller (ADF), Phillip-Perron (PP) tests (Dickey & Fuller, 1981; Phillips and Perron, 1988), and McKinnon (McKinnon, 1991) critical values will be used for that purpose. Second, for appropriate lag length, the VAR process in conjunction with Aikake Information Criteria is used. Third, the cointegration test are applied to detect the presence of any long-term relationship between variables, For two series to be cointegrated, both need to be integrated of the same order, 1 or above. If both series are stationary or integrated of order zero, there is no need to proceed with cointegrations since standard time series analysis would then be applicable. If both series are integrated of different order, it is possible to conclude non-integration. Lack of integration implies no long-run equilibrium among the variables such that they can wander from each other randomly. Their relationship is thus spurious. For *k* endogenous variables, each of which has one root, there will be 0 to *k-1* cointegrating relationship by using the Residual Based approach proposed by Engle and Granger (1987) and the Maximum Livelihood developed by Johansen and Juselius (1990). Finally, the causality amongst the variables is studied by applying the statistical concept of Granger Causality which does not imply any cause-and-effect relationship in a philosophical sense. It refers strictly to the concept of predictability (Granger 1969,1980,1981), meaning that a variable X enables better predictions to be made for Y, *ceteris paribus*. Vector Error Correction (VEC) models were estimated to infer the number of lag terms required to obtain the best fitting model and appropriate lag lengths were then used in causality tests yielding the F-statistics and respective p-values. For any F-statistic, the null hypothesis is rejected when the p-value is significant (i.e. less than 5% level of significance or otherwise). A rejection of the null hypothesis would imply that the first series Granger-causes the second series and vice versa.

The time series include quarterly exports, imports and total trade data on real tens for the period 1990 to 2003 (50 observations) while the data on travel which comprise of total travel, holiday and business travel covers a period of 1987 to 2003 with 88 observations. The choice of data period was mainly motivated by the availability of quarterly data for Malaysia's main trade as well as travel and business partner. Tourism data were obtained from Malaysia Tourism Board (LPM), Immigration Department of Malaysia and Custom Department of Malaysia while the trade data were procured from National Statistic Department and International Financial Statistic (IFS) database. All trade data were converted to real terms and for conversion of aggregate figures (i.e. total exports and imports), a respective export and import indices are used. For regional and country figures, conversion was made by using respective consumer price indexes in absence of export and import indices. All data were seasonally adjusted and logarithmic transformations were made before applying the statistical procedures.

EMPIRICAL RESULTS

Pairwise analyses were made for travel and trade series and their components which is business and holiday arrivals for the former and export and imports for the latter. All tests were carried out for five data sets (Total Trade Malaysia, ASEAN, Australia, UK and USA) reflecting Malaysia's tourism and trade data at aggregate and selected regional or country levels. The selected regional and/or country represent main trade partners. Table 1 shows the results of unit root test (both DF and ADF) and it is clear that all series are integrated of order 1 or I(0) except for Malaysia's real export to Japan and her real imports from Australia and USA. It should be noted here that the DF test is not valid when serial correlation is present in this model. The ADF test for a unit root extends the DF test to allow for richer dynamics in the data generation process when the variable is serially correlated. The lag length of ADF test was left unconstrained to give sufficient degree of freedom so as to allow the error term of the test equation to be serially uncorrelated. For further evidence on order of integration, Phillips-Perron (PP) tests is conducted and the results were virtually identical. The only exception was the real import series for ASEAN that was found to be I(0) by this new test.

Table 1: Summary of Order of Integration

	Total Trade	ASEAN	Australia	UK	USA
Total Arrivals	*I(1)*	*I(1)*	*I(1)*	*I(1)*	*I(1)*
Holiday Arrivals	*I(1)*	*I(1)*	*I(1)*	*I(1)*	*I(1)*
Business Arrival	*I(1)*	*I(1)*	*I(1)*	*I(1)*	*I(1)*
Real Total Trade	*I(1)*	*I(1)*	*I(1)*	*I(1)*	*I(1)*
Real Imports	*I(1)*	*I(1)*	*I(0)*	*I(1)*	*I(0)*
Real Exports	*I(1)*	*I(1)*	*I(1)*	*I(1)*	*I(1)*

Cointegration tests by using both residual and maximum likelihood methods were then conducted for data series of same order of integration and the results are displayed in Table 2. Altogether, as many as 13 pairs of cointegrating series were discovered 4 cointegration each for Australia and USA, and 3 for aggregate total trade series for Malaysia and 2 for United Kingdom. It was quite surprising that no long-term systematic relation was found to exist between Malaysia's trade and tourism with ASEAN. The volatility in the data seems to have marred the possibility of any regular co-movements in the two series. The region currently accounts for more than 40% of Malaysia's arrival and about 45% of the country's trade.

However, systematic relationships seemingly exist between Malaysia's other partner in trade such as United States, Australia and United Kingdom. Another interesting pattern discovered by cointegration tests is that it is holiday travel rather than business travel that is intimately connected with trade and its components. Only 2 out of 13 cointegrating series involved business travel and the rest were either for holiday or total arrivals with clear preferences on holiday travel in defined relationship.

In order to study the causal implication as well as direction of cointegrating series, the causality tests are run for all the series. Since the causality can also be implied by non-cointegrating series, it is therefore being included in the causality test and it done in the sense of Granger Causality Test and the result is summarised in Table 3.

Table 2: Summary of Cointegration Results

Relationship	Category
Total Travel ↔ Total Imports	Total for Malaysia
Total Business Trace ↔ Total Imports	Total for Malaysia
Total Holiday Travel ↔ Total Imports	Total for Malaysia
Total Trade ↔ Holiday Travel	Malaysia and Australia
Exports ↔ Total Travel	Malaysia and Australia
Exports ↔ Holiday Travel	Malaysia and Australia
Business Travel ↔ Imports	Malaysia and Australia
Total Travel ↔ Exports	Malaysia and UK
Holiday Travel ↔ Imports	Malaysia and UK
Total Travel ↔ Total Trade	Malaysia and USA
Total Travel ↔ Imports	Malaysia and USA
Holiday Travel ↔ Imports	Malaysia and USA
Total Trade ↔ Holiday Travel	Malaysia and USA

It is evident that most cointegrating series also display causal relationship which is highlighted by bold prints in Table 3. The vast majority of the causal connections are only one-way. Again, from the result, we can see overwhelming evidence of systematic relationship between business travel and trade as well as its component. The causality can run both ways, for example, imports to holiday travels and holiday travel to imports in the case of aggregate data of Malaysia, and from trade to travel and travel to trade and from travel to imports and imports to travel in the case of USA data. It mush be emphasised that US represents Malaysia's most stable trade as well as travel partner and the American visitors over the years have generated a significant trade flows between two countries and at the same time growing trade between two nations have also led to a surge in visitors arrivals in the city in Malaysia.

While the results reconfirm the close link between Malaysia and US, they also show the importance of Malaysia's other travel market such as Australia and United Kingdom in creating useful trade linkages. Although cointegration results failed to establish any long-term relationship between Malaysia's travel and tourism in ASEAN region, the causality test discover a few weak causal connection, which at around 10% significant level, mainly looking at total travel causes imports, holiday travel causes total trade, holiday travel causes imports and business travel causes exports.

Table 3: Summary of Causality Test Results

Category	Identified Granger Causality Relationship	Sig. Level
Total for Malaysia	Total Travel → Total Trade	10%
	Total Trade → Total Travel	10%
	Total Travel → Total Imports	1%
	Total Travel → Total Exports	10%
	Holiday Travel → Total Trade	10%
	Holiday Travel → Total Import	1%
	Holiday Travel → Total Exports	5%
	Total Trade → Business Travel	1%
	Total Imports → Holiday Travel	5%

Malaysia and UK	Total Travel → Total Trade	10%
	Exports → Total Travel	10%
	Total Travel → Exports	5%
	Holiday Travel → Total Trade	10%
	Business Travel → Imports	5%
	Holiday Travel → Exports	10%
	Total Trade → Business Travel	5%
	Imports → Business Travel	1%
	Exports → Business Travel	1%

CONCLUSION

Although the result tend to differ across trading and travel partner, the study provides strong support that there is a long term relationship between holiday travel in Malaysia and total trade and the causality between trade and travel may run both ways, holiday arrivals influence trade and vice versa. Business travel, although has a few significant causation on total trade, is found to be rather important but not as important as holiday travel as the relation to trade is concern. The results seem to have important policy implication for Malaysia, which has always been adopting an open-door policy with regards to tourism and trade. The main focus of Malaysia's tourism policy in the future and it should be shifted on to generation of more tourism-related businesses and facilities which are relatively higher value added. It should also increasingly turn its attention to emerging meeting, incentives, conferences and exhibition market by developing more of its convention facilities as well as increasing the awareness of eco-tourism towards tourist from the main trading partners. Although there is a suggestion that tourism in the region should be promoted as a specialization, it is not profitable to Malaysia. Since Malaysia has the facilities in both business and holiday businesses, it should concentrate on area but the concentration should be more on the recreational resort and eco-tourism facilities.

The study suffers from standard limitations that apply to any empirical exercise. The results are highly sensitive to data period selected, the size of sample, the quality of data, type of cointegration and causality tests and the omitted variables. All inferences drawn from statistical results should therefore be viewed with caution. Notwithstanding the limitations, the study makes a useful contribution to the understanding of linkages between trade and tourism.

Joint Purchase Decision on Vacation (specialty product) by Spouses:
The Impact of Cohesion and Power-Based Families

ABSTRACT

The majority of family decision-making studies have operationally viewed family decision making as being one of three categories: husband-dominant, wife-dominant, or joint decision between husband and wife. Although a number of studies have recognized joint decision between husband and wife, none of these has considered the impact of family structure on joint decision between spouses. In this research, a field survey of 103 couples in Kota Kinabalu, Malaysia, was conducted to understand the impact of family typing namely, strong vs weak cohesive family and modern vs traditional family on joint purchase decision on vacation (a specialty product) by Malaysian spouses, as well as the moderation effect of joint product usage. The results show that strong cohesive families make more joint decision on vacation than weak cohesive families. Modern families make more joint decision on vacation than traditional families. Joint usage does not moderate the relationship between family structure and joint purchase decision.

INTRODUCTION

Two structural dimensions are often used to describe the type of family - power and cohesion (Holdert, & Antonides 1997). Holdert and Antonides classify family into traditional and modern, based on power, and into weakly and strong cohesive families based on cohesion. These family types often determine how purchase decisions are made, for example, whether by the husband, or the wife, or both. While the concept of consumer socialization has been well researched, the integration of this concept into the family decision framework particularly understanding the role of family structure has been neglected and may provide additional insight into this phenomenon. This information is vitally important for marketers targeting families, in designing effective promotional and selling strategies. It is the aim of this study therefore, to examine the influences of these family types namely, strong and weak cohesive families as well as traditional and modern families, on joint purchase decision of Malaysia spouses on vacation. Vacation has been identified in the literature as jointly decided by spouses.

LITERATURE

Murdock (1949) proposed that family had four essential functions: (1) socialization, (2) economic cooperation, (3) reproduction, and (4) sexual relations. Among these functions, Reiss (1965) found that socialization is the most prevalent function in the nuclear family. For the purpose of this study, family is defined as "a group of two persons or more related by blood, marriage, or adoption and residing together" (U.S. Census Bureau 1978). This definition is suitable for the current research in that it describes membership of the family structurally rather than functionally. The family is considered as an important decision-making unit, due to the large quantity of products and services that form part of the everyday life of a household. According to Cox (1975), the individual members who make up the family unit exercise an influence over each other's behaviour and, therefore, over the activities which form part of consumer decision-making.

The structure of the family consists of the long-term properties of the relationship between family members. Family dynamics consists of the interactions between family members (Kirchler, 1989). Several authors have attempted to describe families by means of specific variables. For instance, Olson et al. (1989) distinguished cohesion, the ability to adapt, and communication style. Fitzpatrick (1984) described autonomy versus interdependence, conflict-involvement versus conflict-avoidance, and convention versus tradition. Kirchler (1989) argued that in order to comprise all these factors, two underlying structural dimensions could be distinguished: power and cohesion.

In the literature, there is no single definition of power. However, there is agreement about the difference between potential power and power actually exerted, called influence (Corfman & Lehmann, 1987). Potential power is the ability of a person to change the attitudes, opinions or behaviour of other people. Influence is the consequence of the active or passive exercise of power. In a relationship, the division of power has been described as traditional versus modern, considered to be a continuum. The distribution of power in the relationship affects the way decisions are made.

According to Ferber (1973), the responsibility of the husband in traditional relationship is earning the money whereas the wife is responsible for the housekeeping and childcare. Davis (1976) claims the existence of large authority difference in traditional relationships. This may frequently take the form of a hierarchical structure. According to Hagenaars and Wunderink-Van Veen (1990) a strictly hierarchical family has a patriarchal structure where the husband and father are considered the head of the family. Kirchler (1989) states that many decisions in a traditional relationship are taken autonomously by one of the spouses. Also, in traditional families coalition formation is likely, as the 'weak' partner will try to find support from other family members. Modern relationships are characterized by a high degree of joint participation in carrying out tasks and taking decisions (Davis, 1976). Hagenaars and Wunderink- Van Veen (1990) state that husband and wife have equal influence in a modern relationship. Also, the power distance between parents and children is shorter in modern than in traditional families. Kirchler (1989) states that in egalitarian relationships, spouses decide much less by role-segregation than in traditional relationships. However, both spouses wish to fulfil their individual desires. As a consequence, many decisions are made together but conflicts arise due to different opinions.

The second underlying structural dimension is cohesion, which is considered a continuous dimension. Cohesion is indicated by the degree of harmony in a family, the degree of interest in each other and the coalition dynamics. In general, cohesion includes the (degree of) emotional bonds between family members. Research has shown that a higher degree of cohesion is associated with a more harmonious family life and less egoistic decision making by the family members (Kirchler, 1989). Table 1 characterizes the different family types.

Table 1: Classification of Family Types

Traditional type	Strong, traditional role-differentiation
	Autonomic decision-making
	Coalition formation
Modern type	Equal division of power between partners.
	Short power distance between parents and children
	Joint decision-making
Weakly cohesive type	Low interdependence
	Disharmony
	Egoistic, individually driven
Strong cohesive type	Strong interdependence
	Harmony
	Altruistic, consideration for others

MALAYSIAN FAMILY STRUCTURE

Kling (1996) reports that Malaysia is an example of a culture with strong sibling obligations. The father is empowered to protect and look after his domestic family. Kling (1996) reports that the study of Malay family and its ideology has to start with an understanding of the interlinkages of three basic foundations: the traditional sociocultural configuration which is internally understood as "adat", the impact and accommodation of Islamic religious principles and the influence of British colonial legislative laws. Compounding three major influences is the current direct exposure of family members, especially the younger generation, to foreign familial interaction pattern as portrayed, rightly or otherwise, by the mass media. The electronic media, especially, brought in an alternative structure of interaction in a pattern of family socialisation for the younger generation and create a sort of structural gap in the situation of family life.

Among the Chinese community, the pattern of obligations is closer to that found in China than to Malay traditions. The oldest sibling has the greatest responsibility by right. Michael and Diana (2003) examine some of the cultural and psychological assumptions of the Malaysian-Chinese people, in particular how their collectivist outlook affects emotional display, manners, family relations, work, wealth and spirituality. The Malaysian-Chinese culture is collectivist rather than individualistic (Markus & Kitayama, 1991; Lu, Gilmour, & Kao, 2001). Since the path to survival is through co-operation with others, the group is valued above the individual. Everybody contributes, anybody might be sacrificed, and personal desires are suppressed in favour of group harmony. Collectivist cultures are more socially oriented, demonstrating less personal independence and more consideration for the general community than is usual in individualistic cultures (Price & Crapo, 2002).

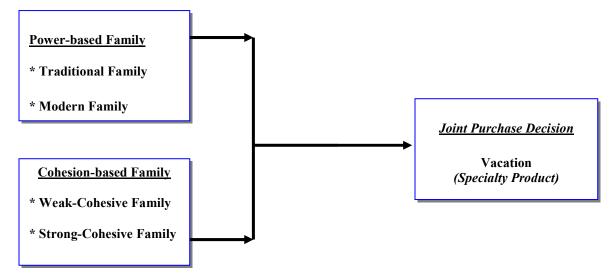
Sidin (1994) uncovers the patterns of family decision making in Malaysia and investigated whether the influence of wives varies with factors such as social class and cultural groups. Two hundred and forty couples in four different cities in Malaysia were interviewed regarding their roles in decision making for purchases of furniture, electrical appliances, and groceries and eating out. Role structure was found to be product specific. Wives' influence in the decision making process was found to vary across social class and cultural groups for the purchase of groceries.

Joint Purchase Decision

Firms must be aware of family purchasing behaviour, in order to implement appropriate marketing strategies. The differences as to who makes the decisions within the family can be determined by different variables, which will show how the power relations within the family unit are produced. It is of interest, therefore, to know who exercises influence in each decision that is made. Within this context of family decision-making, this paper concentrates exclusively on the study of the influence exercised by the spouses in vacation decision.

A number of prior body of research has concluded that the amount of influence depends on the family/household characteristics (Howard & Madrigal, 1990). Scanzoni and Szinovacz (1980), focusing on traditional versus modern sex roles found that traditional sex roles were sharply different and rigid, and tend to make family decision-making quite simple; that is the expected behaviours of the husband-wife are quite clear. In the more modern sex role, the behaviours of each spouse are becoming less predictable because of the increased flexibility and freedom associated with the role. In a study of changing female roles on family purchase patterns, Green and Cunningham (1975) found that husbands of modern wives tend to make fewer purchase decision than husbands of traditional wives. Schwenk (1983) also reported similar findings. Yet there remains a big research vacuum addressing the role of family structure on joint decisions made by spouses. Since joint decisions are becoming more and more common due to the changing family structure, it is therefore of urgent need to address this issue of key family structural influence on jointly decided products. This need is addressed in the current work with a focus on specialty product (vacation).

Specialty products are consumer products and services with unique characteristics or brand identification for which a significant group of buyers is willing to make a special purchase effort (Armstrong & Kotler 2003). Examples include vacation destinations, specific brands and types of cars, high-priced photographic equipment, designer clothes, and the services of medical or legal specialist. Vacation, for example, is a specialty product because buyers are usually willing to travel great distances to buy one. Buyers normally do not compare specialty products. They invest only the time needed to reach dealers carrying the wanted product (Armstrong & Kotler 2003).

METHODOLOGY


From the literature, two structural dimensions of the family are distinguished: power and cohesion (Kirchler 1989). From this distinction, four family types used in this research were identified – the traditional family, the modern family, the weakly cohesive family, and strongly cohesive family (Holdert & Antonides, 1997). The dependent variable is final purchase decision on vacation. This is the third and final stage of Davis and Rigaux's (1974) three stages of the family decision-making process, the first two being problem recognition and information search, both of which are beyond the scope of this research. The specialty product chosen is vacation, because it has been identified by prior body of research (e.g. Davis & Rigaux 1974; Holdert & Antonides 1997; Belch & Willis 2001) as jointly decided by husband and wife.

With this in view, the following two hypotheses were developed for testing:

Modern family will make more joint purchase decision on vacation than traditional family (hypothesis 1).

Strong cohesive family will make more joint purchase decision on vacation than the weak cohesive family (hypothesis 2).

Figure 1: The Schema of the Influences on Joint Vacation Decisions.

Questionnaire was used in the study. The population of the study is married couples in Kota Kinabalu, Sabah, Malaysia. The list of married couples registered with the Statistic Department in Kota Kinabalu, Malaysia was used as the sampling frame. The responding couples were randomly chosen from the list. Questionnaire was distributed personally and through the post mail to the selected families. Request to spouses to complete the questionnaire separately and independently was included in the questionnaire. The purpose is to help check any influences each spouse's opinion might have on the other.

Validate items from previous studies was used to measure the study constructs. The questionnaire is of four parts. In the first and second parts, joint family purchase decision and family structure were determined, with items adapted from Moschis and Moore (1979) and Carlson et al (1990). To categorize families into these types, statements were assessed by means of a four and five point Likert scales respectively. Then following Moschis and Moore (1979) the scales were summed and families classified as 'high' or 'low' on each dimension by splitting up at the median. The third part of the questionnaire contains demographic information about the respondents. Single items were used to measure demographic variables such as age, occupation, gender, education, years of marriage, etc. of respondents. The research data were analysed using the SPSS program. Descriptive statistics were generated to explain the profiles of the respondents. Multiple regression analysis was used to predict the construct relationships.

RESULTS AND DISCUSSION

A total of 206 usable questionnaires (103 sets) were collected and analysed. Table 4-1 below shows the profile of the respondents. There is equal number of male and female responses, 50% are female and 50% are male. This equality was achieved by a deliberate effort to get both spouses to respond. Since the instrument was sent in a set of two to both spouses, they were instructed to fill them out independently. On aggregate the age of the respondents are as follows: below 40 years (68%), 40 years and above (32%). The races of the respondents are Malay (14%), Chinese (35%), Kadazan-Dusun (21%) and bajau & murut (13), others (17%). All the respondents are married. The length of period of marriage are as follows: less than 2 years (38%), between 2-10 years (32%), 11 years or more (30%). The educational background of the respondents is as follows: non-graduates (58%) and graduates (42%). The annual income of the respondents is below RM20,000.00 (19%), RM20,000 to RM39,999.99 (25%), 40,000.00 to RM59,999.99 (23%), RM60,000.00 to RM79,999.99 (15%) and RM80,000 and above (8%), no income (11%).

Table 2: Profile of The Respondents

Variables	Categories	Frequency	Percentage
Sex	Male	103	50
	Female	103	50
Age	Below 40 years	140	68
	50 years and above	66	32
Race	Bajau & Murut	27	13
	Malay	29	14
	Kadazan-Dusun	43	21
	Chinese	72	35
	Others	35	17
Years of Marriage	Less than 2 years	78	38
	2-10 years	66	32
	11 years or more	62	30
Education	Non-graduate	119	58
	Graduate	86	42
Annual Income	Below RM20,000	38	18
	RM20,000-RM39,999.99	51	25
	RM40,000-RM59,999.99	47	23
	RM60,000-RM79,999.99	30	15
	RM80,000 and Above	16	8
	No income	23	11

RELIABILITY OF MEASURES

The reliability test was done on the items measuring the following dimensions: joint decision-making on specialty product (vacation), cohesion-based family, and power-based family. The Cronbach Alpha for all the items are well above .60 'floor' recommended by Hair at al (1998), which indicates high reliability. Table 3 below summarizes the results of the reliability test of the variables, mean and standard deviations.

Table 3: Statistics of the Composite Variables

	No of Items	Mean	S/D	Cronbach Alpha
Specialty product decision	3	3.62	1.01	.9142
Cohesion-based family	4	3.59	1.04	.9065
Power-based family	4	2.88	.74	.8522

Hypothesis Testing using Multiple Regression

The multiple regression analysis was employed to test the construct relationships. This section presents the results of the multiple and hierarchical regressions used to test the hypotheses stated in this study. Hair et al., (1998) see regression analyses as by far the most widely used and versatile dependence multivariate technique, applicable in every facet of business decision-making, hence the study's choice of regression model to analyse the relationships. The assumptions of regression analysis were tested to ascertain non-violation: (1) linearity of the relationship, (2) constant variance of the error terms (homoscedasticity), (3) independence of the error terms (no autocorrelation), and (4) normality of the error term distribution.

The four basic assumptions were met. Firstly, linearity was assessed through an analysis of residuals and partial regression plots, which does not exhibit any non-linear pattern to the residuals, thus ensuring that the overall equation is linear. The next assumption deals with the constancy of the residuals across values of the independent variables. The analysis is again through examination of the residuals, which shows no pattern of increasing or decreasing variations in the residuals. The third assumption is about the effects of carryover from one observation to another, thus making the residual dependent. It is confirmed that there is no auto-correlation problem (i.e. the error term in the independent variables are not correlated). This was checked by looking at the Durbin-Watson values to confirm that they fall within the acceptable region of 1.5 and 2.5, as any value outside this range indicates the presence of auto-correlation problem in the regression. For the forth assumption, a check for normality of the error term was done by a visual examination of the normal probability plots of the residuals, and the regression variate was found to meet the assumption of normality. To check for outliers (i.e. cases falling at the outer ranges of the distribution that may be potentially biasing the results), a threshold of 3 standard deviations was used for the residuals, which is appropriate for our sample size of 206 (Hair et al., 1998) to identify outliers. All observations outside this range (3σ) were considered outliers and were duly dropped from the regression.

Categorization of family types follows the method used by Moschis and Moore (1979) and Carlson et al (1990). The scales were summed and families classified as high or low on each dimension by splitting up at the median. Below the median are traditional families and weak cohesive families, and above the median are the modern and strong cohesive families. Dummy variables were created before using the family categories in the regression analysis. These are the independent variables used to account for the effect that different levels of a non-metric variable (family types in the present case) have in predicting the dependent variable (Hair et al 1998). In creating the dummy variables, the first step was to decide the number of dummy variables, which is simply $k – 1$, where k is the number of levels of the original variable. In this instance $2 – 1 = 1$ dummy variable was created as follows:

(a) Weak cohesive family = 0 (un-coded variable) & Strong cohesive family = 1 (coded variable).
(b) Traditional family = 0 (un-coded variable) & Modern family = 1 (coded variable).

Standardized beta coefficients were reported in this research. This is because standardized regression coefficient allows for a direct comparison between coefficients as to their relative explanatory power of the dependent variable (Hair et al. 1998).

Hypotheses Testing

Table 4 shows the results of the regression analysis used to determine the relationship between family structure (cohesive and power-based family) and decision on specialty product (vacation). The results show that family structure contributes significantly (F = 67.92; p < .001) and predict 41% of the variations in joint vacation purchase decision.

Details of the results show that the coded variables namely, strong cohesive family (t = 5.64; p < .001) and modern family (t = 4.20; p < .001) are respectively more significantly positively associated with joint vacation decision as compared to weak cohesive and traditional family. The results indicate that strong cohesive family significantly makes more joint purchase decision on vacation (specialty product) than weak cohesive family. Also modern family make significantly more joint purchase decision on vacation than traditional family. These confirm the validity of hypotheses 1 and 2. The study shows that there is a significant relationship between family type and joint purchase decision on vacation. The coefficient of determination shows that family typing explains forty percent of the changes in joint decision on vacation.

Table 4: Impact of Family Structure on Joint Decision on Specialty Product

Independent variables	Beta coefficients	t-value	p-value
Dummy for cohesive-based family	.400	5.637	.000
Dummy for power-based family	.298	4.197	.000

R^2 = .401   F = 67.916   Sig. F = .000
Dummy definition: Weak cohesive = 0;   Strong cohesive = 1
Traditional family = 0;   Modern family = 1

It is observable, that strong cohesive family, make significantly more joint decision on vacation than weak cohesive family; and modern family make significantly more joint decision on vacation than the traditional family. Thus, the degree of emotional bonds between spouses and the degree of potential and actually exerted power is an important factor of joint purchase decision. Strong cohesive families, known for strong interdependence, harmony, and high consideration for others, make more joint decision on vacation, such as where to go, when to take a vacation, and how much to spend on the vacation than weak cohesive families marked by low interdependence, disharmony, egoism. Similarly, families exhibiting equal distribution of power between spouses, short power distance, etc. tend to make more joint decision on vacation than families marked by strong traditional role differentiation, male domination, etc. atypical of a modern family.

The results presented above show that family structure is a very important factor in making joint purchase decisions by spouses. Specifically, modern family is more likely to make joint decision on issues concerning the family vacation than traditional family. Strong cohesive family is more likely to make joint purchase decision on vacation issues than the weak cohesive family. These reflect the robustness of family typing in determining whether purchase decisions are made jointly by Malaysian spouses.

Clearly, the results show that the type of family established by the spouses will determine to what extent they will make purchase decisions jointly. Thus, the degree of emotional bonds between spouses and the degree of potential and actually exerted power are important factors of joint purchase decision.

IMPLICATIONS AND CONCLUSIONS

These findings support the theorizing of Davis (1976), which argues that modern relationships are characterized by a high degree of joint participation in carrying out tasks and taking decisions. Prior research (e.g. Kirchler 1989) has also shown that a higher degree of cohesion is associated with a more harmonious family life and less egoistic decision making by the family members. The outcome of this research not only supports Kirchler's views but also takes it further by proving that the view holds, even in the decisions on the purchase of vacation.

The research also holds important implications for practitioners interested in the subject of family decision-making. Firstly, the research gives empirical evidence supporting the preponderance of strong cohesive family over the weak cohesive family in making joint decision on vacation, as well as that of the modern family over the traditional family. Thus, promotional efforts by marketers of tourism products should not be addressed to any particular member of the family but to both. The use of exclusive campaigns that are gender-based may not be effective since both couples have equal say in the decision on what to buy, when to buy, and how much to spend. Market segmentation based on gender should be scarcely used (if at all) since there is no real benefit from its usage. Marketers particularly those selling vacation should develop strategies that are not gender bound and strategies that appeal to both spouses when they are targeting modern families and strong cohesive families.

In conclusion, the paper argues that family structure is a key factor in determining joint vacation purchase decision by Malaysian spouses. Specifically, strong cohesive families tend to make more joint purchase decisions than weak cohesive families. Modern families tend to make more joint purchase decisions than traditional families.

ABSTRACT

Evaluation of park users' judgements of a satisfactory park experience can be helpful in understanding park users' needs and wants. This exploratory study demonstrates a new instrument for assessing users' satisfaction of urban parks. From the study, park users' characteristics, visit characteristics, perceptions of park attributes quality, and evaluation of park experience were identified. In addition, the study also reveals that proposed user satisfaction construct can be a useful tool to measure satisfaction at urban parks. The importance of quality experience at urban parks was found at an average, and requires further quality management consideration from park planners and park management teams. However, reflection for repeat studies on adaptation to the construct is highly recommended since this study is a pioneer in the field of urban park and satisfaction.

_____

INTRODUCTION

Local government has provided urban parks as a place for leisure. However, those who are responsible for park management such as park planners and park management teams must be aware of parks' quality which influence users' satisfaction. Specifically, the parks users' needs and wants which may be affected by park attributes and management actions need further consideration if users' quality park experience is an expected outcome from managing an urban park.

Most people could have realized the importance of urban parks as a place for socializing, relaxation, and sports. However, with little to no revenue generated by most urban parks to its providers, the importance of quality management may have always been ignored. Since a review of the literature suggested that very few studies were conducted on urban parks; and no studies were conducted to relate park users and satisfaction, a pioneer study for assessing urban park users' satisfaction is necessary.

More specific, a proposed research is aimed to assess user satisfaction with regards to user characteristics, perception of parks attributes quality, and evaluation of park experience. Comparison between user perceptions from different parks is desirable.

LEISURE

Researchers have varying views regarding the definitions of leisure. The twentieth century literature writings, descriptions, and theories reveals that people give meanings of leisure as blocks of time (e.g. existence, subsistence, discretionary and leisure), activities, state of mind, and holistic/meaning. According to Torkildsen (1986), growth of leisure is very subtle. Thus, it is hard to create clear lines for its development. Coalter et al (1988) state that leisure in the early nineteenth century was encouraged by social and economic changes. More specifically, societies began to be concerned for public health and fitness of the workforce.

Further, Kelly (1982) recognizes three main benefits of leisure, with regards to recreation of people, which are personal, societal, and economic. He argues that personal benefits of leisure are in terms of psychological, mental health, physical health, and human development. Societal benefits on the other hand, involves family interaction, social cohesion, resources economics, and environmental appreciation.

Leisure Needs

According to Torkildsen (1986), personal factors (such as age, stages in life, interests, culture), social circumstantial factors (such as social setting, job, income), and opportunity factors (such as resources facilities, programs, activities) predetermines individual's leisure pattern. He suggests that individual's choices of leisure experience are influenced by the said choice factors.

Moreover, Argyle (1996) claims that marriage affects leisure. He states, "most leisure is now based in the home, and much leisure is done as a couple, rather than individual" (108). Eagles and McCool (2002) demonstrate that effective management of visitors at national parks influences the quality of experiences visitors get. Further, he argues that understanding park visitor's characteristics, motivations and expectations help leisure managers develop programs that enhance quality of experiences and opportunities visitors achieved.

URBAN PARK

According to Gentill (1991), an urban park is "the garden fashion of Victorian England designed to allow passive recreational activities such as strolling along pathways, admiring the floral displays and listening to a band" (123).
People visit a park for various purposes. Thus, it is important for park planners and management teams to understand park attributes that could maximize the visit experience of park users. According to Manfredo et al. (1996), in order for park managers and planners to efficiently manage parks, they must be aware of the park attributes. Eagles and McCool (2002) state that all type of parks requires some kind of infrastructure to accommodate the needs of their users.

Many researchers would generally associate urban park with leisure activities. According to Kuo et al (1998), urban parks and open spaces act as places in cities that improve people's well being and encourage people's involvement in physical activities. In addition, an urban park is created for the use of all people in a community. Park users are usually people in groups according to socio-demographic characteristics, age, ethnicity, and the residential areas these groups are in (Lieberg, 1995; Crawford and Godbey, 1987). Similarly, Zinn and Manfredo (2000) emphasize that the characteristics of park user groups are usually distinct from one another. Some research projects have been conducted in relation to urban parks

Park Attributes

Conway (2000) suggests that safety influences people's visits to a park. According to Coley et al (1997), environmental features such as trees and work repairs influence people's perception of safety at a park. In addition, Briggs and France (1980) suggest that visual quality influences potential use of a place. Similarly, Hammit et al (1994) note that people's park experience is influenced by the visual appearance of the parks. According to Godbey (1985), the convenience of reaching the location of a park determines people's interest in visiting. Likewise, Ditton et al (1983) claim that crowding influence park user's experiences.

Ravenscroft and Markwell, (2000) investigate social and racial integration of minority group park users, and discover no social integration occurred. In addition, La Page (1983) reports that the New Hampshire Division of State Parks use "report cards" to assess the satisfaction of campers at the park. In measuring user satisfaction at an outdoors recreational setting, Noe and Uysal (1997) suggests that expressive and instrumental factors predict overall satisfaction better than expectation and past-use. However, they too based their studies on national parks.

CUSTOMER SATISFACTION

According to World Tourism Organization 1985, (cited in Pizam and Ellis, 1999: p. 327) customer satisfaction is a "psychological concept that involves the feeling of well being and pleasure that results from obtaining what one hopes for and expects from appealing product and/or service". For the purpose of this study, customer satisfaction is assumed to be the user response to the quality of park attributes and park service performance with relation to the leisure experience.

Components of customer satisfaction

According to Barsky (1992), expectation is a standard that consumers use to judge a product or service experience. He notes that this situation involves comparison of the pre-experience standards (expectation) with perception of product or service performance (quality). Martin and Simmons (1999) views expectation as perceived standard or reference point. It is used as a guide in examining decision-making behaviour. In addition, Miller (1977) proposes that expectation is associated with different levels of performance which are" ideal", "expected", "deserved", and "minimum tolerable". In addition, Zeithaml et al (1993) suggests that feeling of satisfaction from an expected service performance is achieved within the range of "Zone of Tolerance" between the "Desired Service" and the "Adequate" (Zeithaml et al, 1993). Experience helps customers generate expectations of likely needs and wants (Cadotte et al, 1987). To explain service quality as a

function of the difference or gap between the expected and the perceived quality, Parasuraman et al (1985) developed SERVQUAL.

Furthermore, Taylor and Baker (1994) suggest that the relationship between service quality and purchase intention is moderated by satisfaction. When both perceptions of service quality and satisfaction are high, the level of purchase intention is at the highest. Baker and Compton (2000) study reveals that performance quality is possibly a more useful measure than satisfaction in assessing behavioural intentions. However, Oh (1999) suggests that intention to repurchase and intention to recommend is a direct outcome of perceptions, value, and satisfaction. Furthermore, recommendation is perceived as word of mouth and it results from perceptions, value, satisfaction, and repurchase intention.

SERVQUAL SCALE

Essentially, in their original version of SERVQUAL, Parasuraman et al (1985) identified ten dimensions for assessing service quality. However, in a later study, Parasuraman et al (1988) find that some of the dimensions suggested earlier overlap with each other. As a result, they suggested the dimensions to be reduced to five as described below:

> Tangibles:
  Visual and physical facilities, equipment and appearance of personnel
> Reliability:
  The ability to perform the promised service dependably and accurately
> Responsiveness:
  Prompt service and willingness in serving consumers
> Assurance
  Employees' knowledge and ability to serve customers
> Empathy
  Special care and attention the firm provides to customers

Each dimension is represented by four or five statements, which appraise customers' perceptions and expectations of service quality. Generally, 22 statements are asked related to a service firm and a retailing organization. The authors suggest that service quality is measured as the difference of scores Q=P-E (Quality=performance minus expectations) within the dimensions.

According to Bojanic and Rosen (1994), the SERVQUAL instrument is highly reliable and valid for use in different service industries after some modifications. However, researchers claim that the gap score is more reliable and valid if it measures perception only (Carman, 1990; Cronin and Taylor, 1992; Babakus and Boller, 1992). Carman (1990) argues that the reliability of the scale can be improved by expanding dimensions across different industries, and wordings and rating scales requires further refinement

HISTOQUAL SCALE

Frochot and Hughes (2000) proposed HISTOQUAL for use in measuring service quality in historic houses. Referring to the SERVQUAL scale, they present five dimensions of service quality that are responsiveness (staff efficiency and properties ability), tangibles (property environment), communications (historical information quality and detail), consumables (side services), and empathy (consideration of visitors' needs).

From their reliability and validity tests, they claim that their tool is useful for measuring service quality for historic properties under a same organization and tracking evolution of service delivery. Furthermore, the authors claim that their study confirms the usability of SERVQUAL scale as a useful tool, which needs adaptations when considering new services.

CERM CSQ SCALE

This instrument, developed by Howat et al (1996) was to assess service quality of public sector leisure centres in Australia and New Zealand. The authors present four service dimensions, which are core services, staff quality, general facility, and secondary services in order to represent attributes at leisure centres. Dimensional structure of the instrument is presented in Table 1 below.

Table 1 CERM CSQ Dimensions

CERM CSQ Dimension	Attributes
Core services	Program information
	Start/finish on time
	Activity range
	Organization
	Facility comfort
	Value for money
Quality equipment	
Staff quality	Staff responsiveness
	Staff presentation
	Staff knowledge
	Officials
General facility	Safe parking
	Facility cleanliness
Secondary services	Food and drink
	Childminding

Source: Howat et al (1996, p. 83)

Lentell (2000) claims that CERM CSQ is a useful instrument for assessing service quality at leisure centres. According to him, responses from large sample of customers in the development process make the instrument at an advantage. Essentially, reference of CERM CSQ scale helped him in developing a three-dimensional instrument usable in assessing customer satisfaction in UK local authority leisure centres.

METHODOLOGY

The purpose of this research is to measure user satisfaction at urban parks. This research will be exploratory in nature. It will explore how satisfied park users are with their local parks. Specific to this study, it is assumed that people who visit the park is somewhat reliable in providing their perception of the parks performance. Either they are active users, for example visiting the park everyday and use it or passive user (e.g. just cutting through as a shortcut).

Though the study is best supported by value for money and post purchase, it will be a pioneer study approached through method of user satisfaction. In this study, respondents will be asked to indicate their perceptions regarding the 3 dimensions of park attributes (tangibles, empathy, and accessibility). The lists of attributes for the three dimensions are based on aspects such as physical appearance, environment, transportation, and among others. Items asked to respondents were somewhat based on Parasuraman et al. (1985, 1988) multivariate SERVQUAL scale, Frochot and Hughes (2000) HISTOQUAL scale, and Howat et al. (1996) CERM CSQ scale. Though these scales are not directly used as scale measurement for this study, they are referred to because the nature of the study nearly matches with this research's. Moreover, Attitude on overall quality of the park experience, probability of recommending to other people, and the expectation will also be measured. Important attributes and other prospects related specific to park setting were chosen from Baker (2000) and Uysal and Noe (1997). Only some of the attributes were chosen to suit with the nature of this study.

In addition, this research is experimental. It involves developing a new instrument for measuring user satisfaction at urban parks. It also stands as an opportunity to test the uses of existing service quality and customer satisfaction measurement scales in a non-profit leisure setting. Otherwise, the usual leisure setting would normally be subjected to profit based organization. Based on the purpose of this research, three main objectives were established by the end of this research. These objectives are:
  - ➢ Determine if a three dimensional service quality scale, which was inspired by SERVQUAL, HISTOQUAL, and CERM SVQ is valid and reliable for assessing user satisfaction at urban parks.
  - ➢ Identify user and visit characteristics to urban parks
  - ➢ Investigate user perceptions of park attributes quality.

RESEARCH INSTRUMENT

Questionnaire design that revolves around three dimensions (tangible, accessibility, and empathy) was used to assess user satisfaction. Nine statements related to physical appearance and physical value of the park environment, equipment, facilities, safety, education, plants and flowers, and games are presented for the tangible dimension. Four statements present the accessibility dimension. The statements are related to access to the park by public transport, parking space, signage and bulletin. Moreover, empathy dimension refers to how the park management considers disability, age groups, crowding, lighting, and opportunity for leisure. For this dimension, six statements are presented. All the statements for the three dimensions are placed randomly to reduce order bias.

Both nominal scale and interval scale is used for this study. Likert type scale is used as attitudinal measure on the park attributes, overall quality, intention to recommend, and expectation. On the other hand, linear numeric is used in evaluation of the park importance. Moreover, test and retest reliability and parallel form reliability are used to test the stability of measure. In testing internal consistency reliability of different items measuring the same variables, Cronbach Alpha coefficient is used.

In testing for validity, Pearson Product Moment and correlation analysis is used. For construct validity, all variables of the three dimensions (tangibles, accessibility, and empathy) were first tested using convergent validity and discriminant validity. Criterion related validity, which involves concurrent validity and predictive validity was tested in part III of the questionnaire.

DATA COLLECTION

Primary data collection is done at Woking Park in Woking, Manor Park in Aldershot, and Stoke Park in Guildford. All parks are uniquely located. Stoke Park is located near to the University of Surrey; Manor Park houses a military base; and Woking Park is near to Woking, town of many Asian residents. These characteristics may enable researcher to make comparison of the result and add significance to the study.

Non-probability convenience sampling of the resident living in close proximity to the three parks is adopted to increase data accuracy. The meant proximity for this study is assumed as living within ten minutes drive to the park. Essentially, sample unit would be an individual who visits the park for any reasons. Each park will stand as the nucleus of the parameter being approximately 2 miles.

Sample size of 115 respondents was determined for this study. In addition, SPSS (Statistical Package for Social Science) version 11.0 is used to generate descriptive statistics and association between the variables involved. Frequency distributions show the measures of central tendency (mean. Median, mode); measures of dispersion (range, standard deviation and coefficient of variation). Moreover, to assess the relation of variables in each part, inferential statistic is adopted. Independent t-test is also performed on some of the demographic data to reveal if two different groups such as male and female have any significant different in their perceptions with the variables.

A pilot study was conducted to detect any possible shortcomings in its comprehension and to confirm its suitability for use. Thus, the sentences were revised. Few more park attributes were also added to increase the significance of the study outcome. Descriptive statistics of the pilot study shows that mean of the dimensions (tangibles, accessibility, safety, and empathy is between 3.5 to 3.8. Which means that respondents perceive the park attributes is somewhat not satisfactory. From the result of the pilot study, it is confirmed that the measurement scale is reliable and valid.

DISCUSSION AND FINDINGS

T-test and One Way ANOVA was used to analyze the significant difference for respondents' perception of the parks' experience. As indicated from table 2, there are significant differences between all three parks in all aspects except perception of overall importance of park. Interestingly, all parks score the highest for intention to recommend. In addition, the lowest mean score is for total empathy except for Guildford, which has the lowest mean score for total tangible.

Table 2: One Way ANOVA for Overall Park Experience

	Woking	Aldershot	Guildford	S. D	Sig.
Overall quality	5.3	4.6	5.7	1.2	0.01
Recommendation	5.3	4.7	6.0	1.2	0.00
Expectation	4.8	4.5	5.6	1.1	0.00
Total Tangibles	3.2	3.7	2.6	1.0	0.00
Total Accessibility	3.6	4.6	3.2	1.2	0.00
Total Empathy	3.1	3.5	2.8	0.9	0.01
Overall Importance	3.8	4.2	4.1	0.9	0.1

** Correlation is significant at the 0.01 level (2-tailed).
* Correlation is significant at the 0.05 level (2-tailed).

Specifically, Woking scores the highest for overall satisfaction and intention to recommend. Both aspects score 5.3 respectively. Though, the lowest score is for total empathy (3.1). For Aldershot, the highest score is intention to recommend (4.7), and the lowest score is total empathy (3.5). Furthermore, the highest score for Guildford is intention to recommend (6.0), and the lowest score is for total tangible (2.6).

Independent sample t-test used to compare means of perception difference between genders on all aspects of overall park experiences shows that significant difference for both genders is for total accessibility. Specifically, at a confidence level of 95%, only the p-value of total accessibility is at 0.05 and lower. This result shows that gender has an influence on respondent's accessibility to the parks.

Significant differences were also found for age group. Some of the age groups were combined to reach the total number of 25, the minimum valid number for ANOVA analysis. From the result, it is revealed that age influences respondents' perception of overall park importance. With significant value of 0.02 and the mean score of 4.2, respondents aged between 30-39 perceive that park is generally important.

Essentially, these findings can be summarized into characteristics of parks users, their visitation pattern, their perceptions of park attributes, and their satisfaction with park experience. Interestingly, it was revealed that main park users are female aged between 30-39 years old. Surprisingly, these park users are mostly professionals, and people with at least up to GCSE/O level education level. Generally, they are British who perceived their total annual household income of £10,000 to £19,000.

Park users for all parks are quite identical. Difference in characteristics is only evident for Woking. Specifically, Woking park users are usually students, aged between 20-29, and holds master's degree. Not surprisingly, it was at Woking that various foreign nationalities were identified. Aldershot's park users perceived their total annual household income was under £10,000. This significant number may be due to response from military workers, who may perceive their total household income as small. Interestingly, parks users do visit their parks frequently, and spend at least 30-60 minutes to more than two hours during their visits. Indeed, they claim that they usually visit the park during the afternoon, and the main purpose for their visit was for socializing.

Surprisingly, visit characteristics of the park users were different for each park. In Aldershot, respondents visit their park at least once a day during the afternoon for 30-60 minutes. The same visit characteristics apply to Woking, except that the parks users in Woking were not sure about the frequency of their visit. The visit characteristics for Guildford were once a month with time spent at the park for one hour and more. Generally, the three-dimensional scale used in this study for measuring quality of park attributes is useful.

Obviously, park users were moderately satisfied with their parks. Overall satisfaction was greatly influenced by tangible park attributes such as facilities, visual appearance, and surroundings. Other park attributes such as accessibility and empathy does influence their overall satisfaction, but moderately. In addition, parks users see

park accessibility such as transportation, and accessibility in the park itself such as signage was not as they expected. Though, they would likely to recommend the parks to others. The reason for their action would be that not much improvement would be done on the parks.

Though, most park users were somewhat grateful that the government provides the parks for them, they still wish to see some improvements for facilities and equipments. In Woking and Aldershot parks, users wish to have a paddling pool, more playgrounds, more parking spaces, and more equipment such as seating and trash bins. Since Guildford has already have a paddling pool, users wish to see more equipments such as seating, and facilities such as parking space.

IMPLICATIONS

This study as mentioned earlier is exploratory in nature. In an attempt to assess user satisfaction at an urban park, the researcher have used a three dimensional service quality scale containing dimensions of tangible, accessibility, and empathy. These dimensions were proposed after referring to theoretical scales such as SERVQUAL, and HISTOQUAL, and CERM CSQ. Since the proposed user satisfaction construct is reliable and valid, it can be used for future reference on assessing user satisfaction at an urban park. Essentially, this construct can also be used to compare significant difference in user perceptions with their urban parks attributes.

Moreover, this study can be useful for strategic park planners and urban park management teams to understand park users' characteristics, visitation characteristics, and perceptions of park attributes. This study reveals that many aspects regarding park experiences need to be considered by park planners and park management teams. Since the park attributes dimensions mean scores are on the average for tangibles, accessibility, and empathy dimensions score, these people may consider improving mostly all aspects of park attributes at their urban parks. They cannot just provide the parks to people without knowing if what they provided were attractive and beneficial to the park users.

In addition, since parks are used by all people from all demographics background, the park planners and park management teams could provide suitable and enough park facilities. Enough equipment and a healthy environment for park users to have quality experience during their visit to their parks are also important. This study though was successfully conducted were restricted to several limitations. The limitations are characterised as follows:
> *Sample Size*
> The sample size is not enough for producing significant difference in aspects such as gender, age group, and occupation for each park.
> *Data Collection*
> Due to the time constraint and security issue, distribution of respondents for each park was uneven.
> *Park Attributes*
> Since the lists of park attributes were exhaustive, and no previous studies could clearly define park attributes for use in this type of study, some of the important park attributes suitable for this study could have been missed out.
> *Sampling*
> Samples used for this study was selected to represent different social and economic background. But, it was not evident that the parks users characteristics were obviously different.

CONCLUSION

To conclude, this study though with many limitations is somewhat successful. The findings form this study is reliable and useful for use in measuring user satisfaction of urban park. Since very few studies were conducted in assessing user satisfaction at urban parks, future studies specifically focused on urban park and user satisfaction is suggested. As this study is also exploratory and a pioneer of its kind, repeat studies is important. For future studies, it is suggested that adaptations to the proposed construct is made. In addition, researchers should also use a bigger sample size. Careful considerations of other different park attributes is also needed to ensure that users consider park attributes other than suggested to them in this study. Moreover, other parks far away with distinct economic background, and social background could be studied and compared.

Moreover, the findings reveal that respondents' age group, perception of park importance, and gender does influence the respondents' perceptions of accessibility. Furthermore, the findings from this study are valuable for park planners and managers to use as guidelines for managing urban parks that are satisfactory for the users. With the information available from this study, park managers and park planners can devise plans and actions for managing quality urban parks that are attractive and beneficial to the park users.

This study has provided useful research implications for assessing user satisfaction at an urban park. Indeed, findings from this study will contribute to the body of knowledge especially in studies of urban parks and satisfaction. However, since this study is exploratory in nature, and has its limitations due to unavoidable circumstances, reflection of repeat studies is suggested. Essentially, this study reveals that park planners and park management teams need to understand the parks users in providing urban parks to the community. This study too will enable decision makers to understand urban park importance. It is also hoped that many people may realise the value of urban parks and the value of satisfying leisure experience at urban parks. Furthermore, it is also hoped that people from the government would be able to take actions regarding provision of urban parks as a place for leisure.

ABSTRACT

Globally, the concept of sport-related tourism has started to become prominent just in recent years. Instead of traditional tourism attractions and activities mainly based on sun, sea and sand, contemporary tourists are now more interested in activities related to sport that would lead to traveling, feeling of enjoyment, enhancing experience, achieving success or reward, and at the same time be able to boost one's health and fitness. These changing needs in the tourists market has resulted in increase production of sport-related tourism attractions and activities. There are lots of illustration and examples of sport tourism reported in Malaysia that supported the growth of this new sector. Sarawak too is eager to attract visitors by means of sport tourism as one of its major tourism attractions. Basically, sport tourism is a type of leisure-based travel away from home environment temporarily with an intention to watch or engage in attractions associated with sport. Researches have revealed that sport events can bring about many benefits to a destination. With delightful natural environment, fantastic cultural and physical character, available sport infrastructure and facilities, and supportive commercial and public, Sarawak is also promised to be a popular sport tourism destination in Malaysia. In addition, an exploratory tourist survey was performed conveniently to find out about their perception on Sarawak as a sport tourism destination. Perception and insights obtained from the survey were encouraging and supporting the potential of the new tourism in Sarawak.

OVERVIEW

In recent years, special interest tourism of various types has become increasingly popular. One form of special interest tourism, which has captured particular attention, is sport tourism or travels that related to sport activities and/or events. Yet, it is reported that the sport-based tourism (which based on sporting activities or events to attract tourist) has been already in the tourism phenomenon since 1980s and 1990s. As mentions by Bull (1990), it is an area of tourism industry, which has grown considerably during the 1980s and 1990s. The sport tourism events may range from small events to major international sporting activities or hallmark events.

Gibson (1998c) also noted that since 1980s there has been a growing demand for active vacations, especially those related to sport and physical activity. Consequently, during the health and fitness conscious decades of the 1980s and 1990s, entrepreneurs have increased the number of sport tours, developed more sport-specific resort destinations, established specialized sport cruises, added sports activity facilities and programs to hotel or resort, and increasingly promoted sporting events as an attraction for tourists (Gee, Makens, & Choy, 1997).

Originally, the phenomenon of people travel to involve in sport activities has started long time ago, as early as 776 BC to participate in athletic competitions to honor the God Zeus. Additionally, over 3500 years ago the Greeks have initiated the idea of staging athletic competitions (Cook, Yale, & Marqua, 1999). While the original competitions (the Olympic Games) in Greece were organized as contests, the Romans have expanded the idea of these competitions and stage them as games for public entertainment (Cook, Yale, & Marqua, 1999).

Instead of conventional tourism attractions and activities often primarily based on sun, sea and sand, contemporary tourists are now much more interested in activities that would lead to traveling, feeling of enjoyment, enhancing experience, achieving success or reward, and at the same time be able to boost one's health and fitness. Thus, these changing needs in the tourists market has resulted in increase production of sport-related tourism attractions, activities and facilities.

A lot of illustrations and examples have been reported to support the growing of the industry. Many nations have started to develop sport as their major tourism product after realizing the apparent significance that had been generated by the sport industry, which can contribute to the tourism industry (Noel, 2001). A lot of investment and other incentives have been allocated to boost the sport tourism industry. More and more tourism products involving physical and sporting activities and events have been developed. Even Malaysia tries to expand its sport tourism.

While in the state of Sarawak, the tourism industry is experiencing rapid growth over the last decades. Yet, Sarawak has a plenty of tourism resources to offer such as nature, culture based resources which have yet to be fully explored. The tourism industry has been recognized as a significant contributor to the state's economy toward generating economic income and provides employment opportunities. This sector has huge potential to continue to become a major contributor and the driving force of Sarawak's economy in the future, if the state can fully develop the tourism industry. This can be achieved through the development and exploration of more new tourism market.

Realizing the significance of the tourism industry, Sarawak is now in the effort to initiate tourism development to its fullest potential. Currently, it can be seen that most of the tourism products in Sarawak is based on culture and nature. Three major products have been identified to become main tourism strategy in Sarawak in its Second Tourism Master Plan. The strategy includes culture, adventure and nature (CAN). In addition to CAN, ecotourism has become one of the main selling points in Sarawak because of the high quality of its tropical rainforest resources. It has become the popular focus of the state government, and much of the development in the Sarawak's tourism industry is based on ecotourism. Nevertheless, the state's tourism players are still in the effort of diversifying its tourism products in order to give more choices to the visitors.

In Sarawak, the sport-based tourism is considered as a new phenomenon and still an untapped tourism product or market. Most of available sport events/activities cater for the special interest segments only, which necessarily means the sport events were normally small sporting events. However, the state tourism operator is now eager to organize some sport events after realizing the contributions of the sport based tourism, especially in term of its direct economic benefits. The impacts of the sport events being successfully organized in other states might give an encouragement or boost to Sarawak to organize more sport-based events. Examples of events that had been organized successfully in Kuching recently are the annual ITF World Junior Circuit Tennis Masters and Baleh Kapit Raft Safari.

Essentially, Sarawak has wonderful assets especially of nature and adventure. The network of rivers as well as the wonderful mountain range has enabled many sporting activities to be carried out. Most of the water-based sports have been carried out in national parks and other part of Sarawak's forests. Additionally, many sports infrastructure and facilities has been established in Sarawak in recent years. Examples of major sport facilities, which can be found in the state, include a sports complex complete with an indoor stadium, an Astroturf field and an olympic sized swimming pool, state football stadium, Sarawak State Stadium (Indoor Stadium) and golf courses. In short, Sarawak has the utmost potential in promoting sport tourism as one of its major tourist attractions. Together with popular support from related agencies and public, it is not possible for Sarawak to become a popular sport tourism destination in future.

Thus, the objective of this paper is to introduce sport tourism as one of today's attractive tourism sectors. Various aspects and concepts of sport tourism are discussed and applied to the case of Sarawak. In addition, this paper will also aim towards discovering the potential of sport tourism in Sarawak. The assessments are made based on an exploratory research survey of tourists' perceptions, interests and behaviors of the sport-related activities or events in Sarawak. Subsequently, this study may provide basic understanding to the events planners both from public and private sectors to better plan and market the events in the future. Hopefully, this may help to enhance the image of Sarawak as a recognized tourism destination.

THE GROWTH OF SPORT TOURISM

Over the past twenty years, sport is no longer just about playing the game, but it is perceived as a means that provide entertainment to the public, mainly through the radio or television broadcast. Now, it could be one of the attractions that motivate people to travel. Sport-based tourism has experienced an increasing attention from both the media community and academic publications in recent years, especially with the growing coverage of major sporting events (Gammon, 2003). In addition, the opportunities to engage in sport tourism have flourished as a result from the abundance exposure by the travel magazines, newspapers, television and radio commercials that focused on sport and physical activities in diverse destinations, attractions and events.

The growing of the sport tourism industry is mainly due to the rapid changing consumer preferences towards tourism products. Conventional leisure activities such as sightseeing and sunbathing may not always enough for the tourists. Vacationers are now prone to involve or participate in recreational or sport activities during their vacation (Zorba et. al., 2003; Foster, 1991). In 1994, a survey by Marriott International has found that majority of the respondents had viewed opportunity to engage in sports as one of the important factors when selecting a vacation (Gibson 1998a; 1998c). For that reason, it is essential for a destination to meet the constant changes of taste and lifestyle of the consumers as well as fashion trends in order to better targeting the market.

As Gibson, Willming and Holdnak (2003) observed that the last decade of the twentieth century was marked by a growing recognition of the apparent and inherent relationship between sport and tourism, and it is likely to be growing well and continue into the next century. Many countries have shown their interest in developing the sport tourism industry after noting the significance of sports in the tourism industry. Emphasis has been given to the sport tourism sector and the provision of facilities, training, marketing and promotion strategies had been encouraged by the governments in order to facilitate the development of sport tourism.

Australia and United States have recognized sport tourism as one of the most important tourism sector in countries and, plenty of development strategy had been formulated to develop the sport tourism industry. While in Canada, a lot of programs had been adapted by the Canadian Tourism Commission (CTC) since 19966 in order to promote community and tourism industry's interest in the development of sports tourism as a viable contributor to the economic well being of local communities (Commonwealth, 2000). Britain's Department of Culture, Media and Sport has already stressed on the government's intention to develop innovative niche markets such as the sports tourism (Commonwealth, 2000). In South Africa, the sport tourism was being identified as one of the major sectors that needed to be given more concentration.

Apparently, Sarawak too is in the effort of developing its sport-based tourism. Some sports-related attractions, activities and events have already been organized since early 90s, even though noted that most all were primarily based on nature and culture. Generally, the events were able to attract good responds and supports from the locals, domestic visitors and some foreign tourists. The production of events was heightened in 2003 as many sports-based activities/events as well as other touristic events were specially planned and organized as part of Sarawak's first "Tourism Year 2003" program. In terms of sport facilities and infrastructures, many sports infrastructure and facilities have been established in Sarawak such as golf courses, stadiums, swimming pools and courts to support local, national and international sport-related activities/games and events. In recent years, the sport activities and events have started to also include natural settings such as sea, rivers, mount, parks and reserved areas.

SIGNIFICANCES OF SPORT TOURISM

Sport tourism has boomed over the past 20 years. A study conducted by the Georgia Institute of Technology in Atlanta has shown that sports have grown from the 25th largest industry in the United States to the 11th largest (Kelly, 2000). In addition, Kelly (2000) also notes that the community size is irrelevant in developing the sport tourism. Research has shown that even a small town can also have an opportunity to develop the sport-based tourism industry, and such cities or countries might not need a world class facilities or huge budget in order to attract the world.

Basically, the profit and non-profit agency's intention to stage the festivals and events are due to several apparent reasons. Mayfield and Crompton (1995) had identified eight generic reasons why these organizations stage festivals and events: recreation or socialization, culture or education, tourism, internal revenue generation, natural resources, agriculture, external revenue generation, and community pride or spirit (cited in Turco & Lee, 1996). Interestingly, the "community spirit or pride" and "family" were ranked by the respondents as being the most important reasons for staging festivals or events (Turco & Lee, 1996).

A study indicates that success of mega hallmark events can bring lots of benefits to the countries economics and tourism industry (Games BID, 2003). The benefits are as the following:
- Long-term economic benefits from visitors who come as a result of an event's worldwide exposure are larger in total than short-term economic benefits.
- Foster a public sense of economic momentum, which in turn will foster new investment and economic growth.
- Mega events have a profound impact on the international convention business in the host cities. For example, Sydney has increased the number of international convention bids it won by 34 per cent after it was being chosen in 1993 to host the 2000 Games.
- Vancouver and Whistler in particular and British Columbia in general will have their profiles raised throughout the world, and strengthening the tourism industry. For example, before the Calgary winter Olympics in 1988, Alberta had an average annual growth of annual international visitors of 0.25 per cent (1972-1985). In Pre-Olympic years the number of visitors grew by five per cent in 1985 and eight per cent in 1986. In the Olympic year, growth surged to 12 per cent and then retained all of its post Olympics gains, with an average annual growth of 3.25 per cent for the first post-Olympic years. This compared with an average annual lose of 2.5 per cent for the rest of Canada, excluding British Columbia.

- International tourism in Norway increased by 43 per cent between 1990 and 1994 leading up to the Winter Olympics in Lillehammer, probably as a result of increased media awareness generated by the upcoming games.

Obviously, nearly every national or international sporting event is accompanied by claims of huge benefits that accrued to the host cities (Matheson, 2002). Malaysia also has tried to develop the sport-based tourism as one of the new product or attraction in the Malaysian tourism industry after realizing the potential of the sport tourism in attracting both local and foreign tourists. A study by the University of Malaya shown that the 1999 Malaysian Sepang Formula One Grand Prix has brought in more than 20,000 foreign spectators from Europe, Japan and other Asia Pacific countries (Thomas, 2000). Thus, the race has generated US $144 million in the direct spending for the Malaysian economic (Thomas, 2000).

Nowadays, spectator sport is a growing segment of the leisure, recreation, and tourism industries. The US Bureau of Economic analysis estimated that Americans spent $6.7 million in 1997 attending sporting events, compared to $4.5 billion in 1991 (Canon & Ford, 2002). While the 1999 British Open had brought about $20.1m revenue to the local economy through linkages of tourism with other economic sectors (Gelan, 2003).

A study by the Commonwealth Department of Industry, Science and Resources (2000) also found that the sport tourists have a higher yield than other types of tourists as can be seen through the Australian domestic sport tourist that spending 16% more on average per day, with 31% staying in the hotel, resort, motel or motor inn accommodation on their sports trip compared with 23% for all domestic travelers (Jago, 2003; & Commonwealth, 2000). Furthermore, Foo (2000) has found that 6% of daytrips that taken by Australians in 1998 and 5% of the overnight trips were for sporting purposes (quoted in Jago, 2003). Similarly, s study by Bureau of Tourism Research had found that the Australian domestic sports tourists were appeared to generate a higher dollar yield than other domestic travelers, with 31% staying in the hotel, resort, and motel or inn accommodation on their sports trip compared with 23% for all domestic travelers (Commonwealth, 2000). Research by Zorba et.al., (2003) suggest that a successfully executed sports and recreational programs will positively affect the length of time foreign tourist will spend at the lodging establishment, which in turn will increase the income of the recreation area.

Likewise, as sports and recreational activities/events are becoming popular among the Malaysians, tourism industry has realized that the sport-related events can bring a lot of economic benefits to Malaysia. As an illustration, the 1998 Malaysia Commonwealth Games had been reported to generate huge economic benefits to the country. A study by the research division of the Malaysia Tourism Promotion Board during the 1998 Commonwealth Games has revealed that a single international tourist that came for the event has spent an average of RM 307.64 per day or RM 3845.50 for the duration of 12.5 nights stay in Malaysia (Mohd, 1999). Besides, it also helped to raise the country's image in holding large sports events.

Travel by the sports spectators will particularly act as a catalyst for other tourism sector as well as other economic industry. As Gibson *et. al.*, (2002) point out that the fans contribute economically to the host community through their use of food services, accommodations and shopping related activities. Furthermore, Gee, Makens and Choi, (1997); & Mules (1998) stated that travel by spectators to games represents an important market for carriers, the lodging industry, accommodation, and the food and beverage industry, which can bring millions of dollars to the countries or states.

Apart from the economic contribution, the spots events can also contribute to the urban redevelopment and renewal. Hosting sports events is becoming a common strategy for the economic regeneration of many urban communities (Gibson, 1998b). Thus, mega-events could possibly act as a catalyst to urban development. For example in Malaysia, the government has spent US $5 billion to build sporting facilities and other facilities such as roads in conjunctions with the 1998 Commonwealth Games (Musa, 2000). While the Melbourne Olympic Games in 1956 has provided major facilities that contributed to the city's reputation as a sporting center for several decades (McDonnell *et.al.*, 1999).

Similarly, Karlis (2003) has argued that the organizing of the Olympic Games will attract the high-income tourist and attract the new generation of tourists who will make several visits to the host country, create favorable image for the destination, modernization of the tourism infrastructure, to enhance country's image in the international arena and provide a skilled work force. For example, the Sydney 2000 Olympic Games has represented as excellent opportunity to reinforce and consolidate Australia's sport infrastructure, and the infrastructures are catering for participation in sport at all levels and in all forms (Shilbury, 2000; McDonnell *et.al.*, 1999). The Olympics have offered Sydney's entrepreneurs and politicians an event to both reposition the city and to restructure the local economy into a more profitable industry (Waitt, 2003). Besides, Sport events are

also acknowledged as a moments of symbolic significance because of the high level of social interaction they provide, and the intensely personal identification they generate in their audience (Garcia, 2001).

Hosting the international sporting events such as Commonwealth Games, Formula one Malaysian Grand Prix and the Golf World Cup can help to raise the Malaysia's image and ability in offering and organizing excellent international sport events. Furthermore, sports events can help to overcome or cope with the geographically and seasonally circumstances (Gelan, 2003). Additionally, the sport events at the same time can also help to promote the country's other tourist attractions. For instance, the Le Tour de Langkawi (LTDL), the biggest cycling tour outside of Europe, which covered 10 states, can help to promote the whole country. As mentioned by the Minister of Culture, Art and Tourism Datuk Abdul Kadir Sheikh Fadzir, the staging of more international sporting events would promote the Malaysia's capability to host such events and at the same time it can help to promote the country's unique selling points – its diverse cultures, nature and history.

In short, many destinations including Sarawak are aggressively competing which each other to stage international sporting events after realizing its many potentials. These destinations are even willing to spend millions of dollars to organize such events not only for the sake of sport itself but more importantly to get the economic returns through various tourism-related activities and international exposure during the events.

UNDERSTANDING OF SPORT TOURISM

Basically, "sports" are physical activities that controlled by formal or informal rules for fun, recreation or rewards. Both competitive sport and non-competitive sport (e.g. recreational activities) are being included in the term of sport. Meanwhile, "tourism" is a phenomenon where people travel away from their usual environment to get involve in leisure and recreational activities. However, by combining both definitions on the sport and tourism, the term "sport tourism" can be defined as the a phenomenon where people travel away from their usual environment to be involved in either competitive or non-competitive sport-related activities/events for fun, recreation or rewards.

Meanwhile, sport can also be defined from the leisure perspective. As Kelly & Freysinger (2000) say that sport may be is a special kind of leisure, which involved challenge, excitement, involvement, community building, and satisfaction. There are also certain researchers that have defined sport as a cultural experience of the physical activity and challenge includes the ingredients of play, such as it can occur in the sense of spontaneity and the games participant will be facing some uncertainty as they need to compete fairly among each other to get the glory.

Yet, until today there are still no agreed or clear standard of definition that could be used internationally to describe the term sport tourism. This condition is quite acceptable as there is still a doubt whether can or should combine the sport and the tourism, as both are quite distinct from viewpoints of marketing, economic, financial, psychological, and sociological. According to Gibson (1998a) and Commonwealth (2000), some difficulties had occurred in defining the term sport tourism. This is because researchers of various fields have tried to define sport-based tourism from their own insights, which related to their distinct scope of studies. In addition, the complexity in defining the term sport tourism may be because of lack of coordination and cooperation between the sport industry and tourism industry. As Gammon (2003) observes that there is no or little academic communication between those working within tourism sector and those in sport industry.

Nonetheless, according to Gibson (1998a), sport tourism can be defined as one type of leisure-based travel that takes individuals temporarily outside of their home communities to play, watch physical activities, or idolize attractions associated with these activities. In order to simplify everything, Gammon and Robinson (2003) have classified sport and tourism under 2 conditions: "sport tourism" and "tourism sport". It appeared that the main dissimilarity between the two is that the differences in the tourists' primary travel motivations.

Sport tourism - Sport is the prime motivation for the individuals or groups of people to travel, to actively or passively participate in a competitive or recreational sport.

Tourism sport - The holiday or visit is the prime motivational reason for the individuals or groups of people to travel. Additionally, participating, whether actively or passively, in a competitive or recreational sport has become the secondary activity during the travel.

Gammon and Robinson (2003) also described that the categories of sport activities depend on the nature of the visitor and the visit, which is based on the consumer's motivations. However it should be noted that the model (as illustrated in Figure 1) takes no account of repeat visits, age and experience over time. Thus, the typology of the sport and tourism are differing at different times (Gammon and Robinson, 2003).

Figure 1 - A Consumer Classification of Sport and Tourism.

SPORT and TOURISM

Sport Tourism   *Tourism Sport*

Hard definition   soft definition   soft definition   hard definition

| Passive or active participations at a competitive sporting event | Primarily active recreational participation in sport | Visitors who engage in some minor form of sport or leisure; their participation is purely incidental | Tourists who as a secondary reinforcement passively or actively participate in sport |

Furthermore, Thwaites (1999) suggested the characteristics of the sport tourism from both the demand side and supply side. From the supply aspects, the sport tourism is multisectoral and the nature of the product is complex as it represents a mixture of various elements; the highly fragmented supply, in where the businesses may contribute to the overall experience; certain aspect of the sports' product are intangible (Service cannot be seen and touch), inseparability (production and performance cannot be separated and must occurred in the same time), and perishability (services cannot be stored for the next time uses, e.g. ticket to watch the sports events cannot be stored for next games). From the demand aspect, the sport products are highly elasticity; seasonality; changing needs; attitudes and preferences of customers with little brand loyalty; and heterogeneous customer groupings e.g. each customer will have different needs and wants towards the sport events (Thwaites, 1999). Likewise, Turco (2000) has identified several characteristics of the sport tourism, as the following:
-   short duration;
-   high concentration of athletes (participant) and spectators;
-   extensive media coverage;
-   multiple venues, concurrent sessions;
-   uncertainty of contestants, outcomes.

CLASSIFYING SPORT TOURISM

There are a number of ways to classify the sport tourism. One of the approaches is introduced by Gibson (1998a; 1998b & 1998c). Fundamentally, he suggested that there are three major types of sport tourism: "Active sport tourism", "Event sport tourism" and "Nostalgia tourism". As explained by Gibson, active sport tourism refers to the participation in the sport activities away from home environment. Additionally, he had established several characteristics of the active sport tourists, which are likely to be male, affluent individuals, college educated, willing to travel long distances to participate in their favorite sports, likely to engage in active sport tourism well into retirement, and they tend to engage in repeated activity.

The Active sport vacations can be further divided into 3 major types, as mentioned by. The first type is "Pure sport Holiday", where the primary purpose of travel is to take part in sports activities or contests. The second type is "Vacation", where participating in sport is not the primary purpose yet they are making use of the sports facilities. The third type of active sport vacations is "Private sporting holiday", where people take part in informal games such as beach volleyball (Gibson, 1999). Furthermore, the Active Sport tourists could be subdivided into "Activity participants" and "Hobbyists". Activity participants refer to persons that engage in sport related travel as a form of leisure, while hobbyists are the amateur 'players' that travel to take part in competitions in their chosen sports (Gibson, 1998b; & 1998c).

Meanwhile, Events sport tourism is a phenomenon where people are traveling away from their usual environment to watch sporting events (Gibson, 1998a; 1998b; & 1998c). These spectators are normally being included in the sport tourism even though they are only passively involved in the events. In contrast, Nostalgia sport tourism is being described as a type of travel to visit sports halls such as the basketball Hall of Fame in

Springfield, Massachusetts, sports museums, and other famous sporting venues. In other words, the nostalgia sport tourism refers to the people's intention to watch or experience the famous sporting venues such as the architecture of the sports hall of fame and sport museums, which can help them to retrieve back their old memories.

The next approach can be found in literatures written by Gee, Makens, & Choy (1997) and Gibson (1998b) encompassing attractions, resorts, cruises, tours, and events associated with sports and recreation. The following are the definitions on these sport tourism categories:

Sports Tourism Attractions
Sports tourism attractions refer to those attractions that providing "energizing power" with sports related physical activities as their principle focus. This kind of attractions is usually on-location in places within regions, countryside or urban setting, which can provide the tourists things to see and do, where the personal and social expectations could be in varying degrees. The attractions could be natural or man-made such as sport museum; state-of-the-art sport facilities: stadiums, arena, bowl, etc.; hall walls of fame. (Examples in Table 1)

Sports Tourism Resorts
Sports tourism resorts represent well-planned and integrated resort complexes or villas with sports as their primary focus and marketing strategy. Normally, these vacation centers have high standard facilities and services available to the sport tourist. Some of these resort sites focus on specific, highly developed skills, while some cater for the recreational sporting activities. (Examples in Table 1)

Sports Tourism Cruises
Sports tourism cruises refer to the boat trips that have sports or sporting activities as their principal market strategy. General characteristics of the sport tourism cruises include: special transportation for tourists from one land location to another providing opportunities to involve in sport activities; high profile of sports personalities on board sharing discussions, and coaching opportunities for the tourists Sports conference (seminar and special sessions) may also being hosted on board. (Examples in Table 1)

Sports Tourism Tours
Sports tourism tours refer to the companies that utilizing the sporting activities as their primary focus in arranging tours and touring venues. General characteristics of the sport tourism tours consist of: specific visitations to one or more sport attractions over a specified number of days (sport theme park, sport museum, etc.); combined visits to sports attractions and major sports events (heritage sites, walls of fame and sports events); attendance at a specific number of major sports events (professional basketball and golf, in one or more locations); participation in conferences, workshops, clinics, forums, and attendance at major sports events; tours related to the natural characteristics or setting pursued by tourists for aesthetical and / or physical reasons (trekking, regatta, mountain climbing). In essence, the tourists that involved in this category can be classified as "novelty seekers" and "explorers" as they are seeking for authenticity and the quality of sport tourism experience. (Examples in Table 1)

Sports Tourism Events
Sports tourism events refer to those sports activities that are attracting a large percentage of sport spectators. Furthermore, it has the potential to attract non-resident media, technical personnel, athletes, coaches and other sports officials. The distinctions of the sport tourism events are - the tourists are travel to see the sport activities or games; and the tourists are actively participating in the spots activities, whether formally planned or informally organized. (Examples in Table 1)

Table 1 – Examples of the Categories of Sport Tourism

Attraction	*Resort*	*Cruises*	*Tours*	*Events*
Sports museums/ Hall of frame	Sports conference	Sports/celebrity cruises	Facility/sites event tours	Regional/national/int. sport events
Stadiums/arena	Training/Sports camps	Sports attractions visitations	Sports adventure tours	Regattas
Golf courses	Ski resorts	Fishing cruises	Cycle/walking tours	Marathons

Source: Adapted from Tourism Sport International Council 1991, Canada. (Cited in Gee, Makens, & Choy, 1997)

Other than the two approaches described above, the sport tourism can be classified according to its various settings. Essentially, the sport tourism activities could take place in urban and non-urban settings, indoors or outdoors, in all types of climatic conditions and in all settings. Different settings within sports tourism can be classified according to situational locale of the experience and may be identified based on:

(a) "Cultural setting" - where some elements of the sports activities are consists of cultural elements, such as regatta.
(b) "Natural setting" - where the sport events are being conducted in the natural environment, such as mountain climbing, canoeing, and rafting.
(c) "Man-made" setting - where the sport activities are being conducted using the man-made sport infrastructures or facilities, such as stadium, buildings and sport museum.
(d) "Social setting" - where the involvement of the tourists in the sport activities is just for fun, excitement, experience, without any economic benefits.
(e) "Economic setting" - where the sport tourists' involvement in the sports events is for some economic returns. For example, the professional athletes will gain an economic reward if he or she represents his or her own country to participate in the game.

According to Gibson (1998a; 1998b & 1998c), there are two major types of sport tourism available in Sarawak – active sport tourism and event sport tourism. There are various sport facilities built for the locals and also visitors that can support these two types of sport tourism. There are available a sports complex complete with an indoor stadium, an astroturf field and an Olympic sized swimming pool. Other major sport facilities, which can be found in the state including State Football Stadium, Sarawak State Stadium (Indoor Stadium) and a number of world class golf courses. The State Hockey Stadium was officially declared open on June 30 1991 with a capacity of about 1000 spectators. Additionally, a new outdoor stadium (Stadium Sarawak) with seating capacity of 40,000 spectators was built in 1997. The sport facilities include football pitch and–lane synthetic running track as well as other ancillary facilities such as meeting hall and conference rooms.

Variety of special events and festival were organized to attract visitors all year around. Some of the sport events had even established their reputations and are being organized as annual events such as Kapit Balleh Raft Safari, Sarawak Regatta, Borneo Cup Motocross Championship, and Lambir Rainforest Challenge because of tremendous support from the locals and tourists, both locally and abroad. In summary, Sarawak has successfully put together huge efforts to cater various needs and requirements of the Active sport tourists and Event sport tourists. In contrast, Nostalgia sport tourism is a concept of tourism that has yet to be introduced in Sarawak.

Sarawak has several established sports events every year like the ITF World Junior Tennis Circuit, several regattas and nature challenges. From year to year, new and more events and festivals are being introduced and staged by both profitable and non-profitable organizations. Other than that, Sarawak may need to start increase its international events or expand the presents events internationally. In the category of sport attractions, the most popular attraction in Sarawak is its golf courses. Still, Sarawak need to come up with new ideas of sport attractions that can be popularized for tourists, such as sports museums and wall/cave climbing. The available stadiums/arenas need to be managed and marketed strategically. While strengthening its events and attractions, Sarawak can begin developing other categories of sport tourism for the tourists like sports resorts, cruises and tours.

Generally, sport tourism in Sarawak has taken place in various settings - urban and non-urban settings, indoors and outdoors, nature and man-made settings. There were sports events that based on nature (ecosports) and adventure and carried out mostly in natural setting such as Sarawak Similajau Nature Challenge, Borneo Mountain Bike festival, Sarawak Regatta and Sarawak Kubah Serapi International Run. There were also professional sports events like ITF World JR Tennis Circuit, Sarawak International Triathlon and Sarawak JR World Masters Golf Championship. Even the cultural festivals in Sarawak are also incorporating some kind of culturally sport competitions or contest as part of the agenda.

It is no doubt that Sarawak has incredible geographical diversity especially the natural surrounding or environment. The land of Sarawak is richly stream with wonders of the natural world. Two thirds of Sarawak is covered in rich green vegetation, mainly ancient rainforest. The network of rivers as well as the wonderful mountain range has enabled many sporting activities to be carried out. Most of the water-based sports have been carried out in national parks and these natural parks will be the most suitable place for the adventurous to pursue an adventure experience. Each year few of the rivers have become the routes for raft safaris events. Apart from rafting, the natural resources will also facilitate many others sporting activities such as mountain climbing, mountain biking, wall climbing, water skiing, yachting and many others.

SPORT TOURISTS – CONSUMER BEHAVIOR

Generally, a person will be considered as a sport tourist if their primary purpose of travel is to actively participating in or viewing the sport events (Turco, 2000). To be specific, the sport tourist is defined as a

temporary visitor that stay at least 24 hours in the destination visited with the purpose to attend the sport-related events (Commonwealth, 2000).

Collectively, the sport tourists can be divided into two categories, "Domestic sport tourists" and "International sport tourists". According to Commonwealth (2000), domestic sport tourism refers to any sport-related trip that is being taken 40 km away from home and involves at least one night stay. On the contrary, an international sport tourism refers to any sports-related trip that involve travel to other country with a primary purpose to participate in a sporting activity, either as a spectator, participant or official (Commonwealth, 2000). Using the case of 2004 Olympic Games in Athens, Karlis (2003) has tried to categorize the international tourists into three categories: visitors before the games (members of the International Olympic Family, sponsors, media, athletes, and spectators); visitors or spectators of the games (when the games are being held); visitors that are attached to the country due to the publicity (foreign tourists). Apart from the sport tourist, there is another type of sport consumer, which is called "Sport excursionists". Sport excursionists are day-trippers for a sporting event, which necessarily means they do not spend a night on the destinations (Gibson, Willming and Holdnak, 2003; Commonwealth, 2000)

The sport tourists can be further categorized to "Sport spectators" and "Sport participants". Each of them has their own characteristics. Shank (1999) has described the spectators as a consumer who derives their benefit from the observation of the event or watches the events. Meanwhile, the participants are the consumer that becomes actively participated in a variety of sports at a variety of competitive levels (Shank, 1999). Likewise, Pitts (1997, cited in Commonwealth, 2000) has clarified that the sport tourism consists of two broad categories from a sport marketing and sport management perspective, which are:
- Sports participation travel - travel to participate in the sport, leisure, recreation or fitness activities); and
- Sports Spectatorial travel - travel to spectacle the sport, leisure, recreation or fitness activities or events.

In addition, each of the sport tourists has their own objectives to achieve for their involvement in the sport activities or events, depending on their role whether as a participant or spectator. To the athlete-participant, the mastery of the body in particular skill development is implicitly essential. A participant with high level of commitment and team identification will gain eight durable benefits from the games: self actualization, self enrichment, self expression, renewal of self, feelings of accomplishment, enhancement of self image, sense of belongingness and social interaction, lasting physical products as a result of participation, and pure fun (Gibson, Willming and Holdnak, 2002). To the spectators, the degree of skill perfection and discipline demonstrated by the athlete becomes a symbol of perfection, admiration and success. However, these universal needs will be experienced differently and in various measures due to their intellectual, emotional, psychological, and social or other.

Table 2 - Reasons People Participate In Sport

Personal improvement
- Release of tension/relaxation,
- Sense of accomplishment,
- Skill mastery,
- Improved health and fitness,
- Other people's respect for one's athletic skill,
- Release of aggression,
- Enjoyment of risk taking,
- Personal growth,
- Development of positive values,
- Sense of personal pride.

Sport appreciation
- Enjoyment of the game
- Sport competition
- Thrill of victory

Social facilitation
- Time spent with close friends or family
- Sense of being part of a group

Source: Milne, Sutton, and McDonald (1996, cited in Shank, 1999)

Initially, there are several reasons why people participate in the sports activities/events. As Loy *et. al*., (1989) stated, the mass participation in many sporting events is due to a wide range of reasons including fitness, social contact, health performance, dedication to excellence, and in some cases, livelihood (cited in Higham & Hinch, 2002). Specifically, a study by Milne, Sutton, & McDonald (1996) has suggested that there are three basic reasons for people to participate in the sports as noted in Table 2 (cited in Shank, 1999).

Other than personal factors, there are also some other factors that would influence the game attendance. According to Shank (1999), games attractiveness, economic factors, competitive factors, and demographic factors could also affecting the spectators' decision to attend certain sporting events. Games attractiveness is a situational factor that will vary from game to game and week to week depending on individual's perception or expectation towards the events. Basically, the more attractive the game, the more likely attendance will increase (Shank, 1999).

Both the controllable and uncontrollable economic factors could also impact the game attendance. The controllable economic factors include aspects of the sports marketing environment, which can be altered by the marketers, such as the ticket price (Shank, 1999). The uncontrollable economic factors are things such as the average income of the population and the economic well being of the destination (Shank, 1999). The greater the perceived value and the higher the income of the population will lead to greater game attendance (Shank, 1999).

The competitive factors can be either sources of a direct competition (other sport) or indirect competition (other forms of entertainment). Simply, the lesser the competition for the spectator's time and money, the more likely the game attendance will increase (Shank, 1999). Other than that Shank (1999) also had stressed that the demographic variables such as age, gender, education, and ethnic background could also influence the game attendance.

As it can be seen, tourists today are looking for an extra value or benefit when choosing certain travel destinations or attractions. The tourists nowadays prefer to do things they have never done before, desire to visit to new places, travel healthy, have a direct travel experience, have multi-activity trips, accomplish something when they go on vacation. This change of preferences may results from today's improved education and/or modern technological advances. Essentially, the sport tourism could help or boost the tourists to accomplish all their wants and aims during their touring.

SPORTS POTENTIAL IN SARAWAK – THE SURVEY

To determine the potential of Sarawak a sport-based tourism destination in the future, a preliminary survey of tourists' perceptions, interests and behaviors towards the sport-related activities or events in Sarawak was undertaken. A sample of 100 tourists, who have been staying at least one night in Sarawak, was chosen conveniently at several popular tourist locations such as resorts, hotels and airports.

Table 3 - Socio-Demographic of Respondents

Origin	Percentage	Gender	Percentage
Peninsular	58	Male	39
Sabah	14	Female	61
Foreign	28		

Age	Percentage		
Below 20 years	9		
20 – 39 years	65		
40 – 50 years	25		
Above 50 years	1		

As shown in Table 3, Sarawak's tourists market consisted of domestic tourists from Peninsular Malaysia (58%) and Sabah (14%), and the rest were from international market (28%). Among the originating countries of the international tourists were England (21%), Singapore (18%), followed by USA, Japan, Indonesia, Thailand, Australia, Holland, Norway, Scotland, and South Africa. High percentage of the sample was male (61%). Majority of the sample were between 20 to 39 years old (65%) and 40 to 50 years old (25%). Thus through the survey, it could be established that Sarawak attracts younger market of tourists, which may be a good prospective for the sport tourism.

The survey has found several main reasons why the tourists chose to visit Sarawak. The most reason supplied by the tourists was the most basic and conventional touristic experience, sightseeing (27%). Other reasons given

were education (24%), business (19%), and visiting friends and relatives (VFR) (15%). Only a small number of 3% of the survey was reported visited Sarawak with primary motive related to the sport activities/events or in another term "Sport tourism". Thus, Sarawak presently is succeeded to attract only a small portion of sport tourists.

However, Sarawak still has prospect to develop its sport tourism sector. This is because the survey has revealed that even though their main motive of visiting Sarawak was not sport tourism, 25% had disclosed that they have in fact observed or even participated in some kind of sport activities/events during their traveling in Sarawak. Thus, they can be categorized under "Tourism sport" with the holiday or visit as the prime motivational reason for their traveling. And as expected, most people from this group were young and educated male. In contrast, the rest of the sample (74%) had stated that their tight traveling schedule played an important role in deterring them from involving in any sport-related activities/events.

In addition, the tourists were actually interested to be involved in sport tourism. 23% of the survey admitted that they were very interested to participate or watch sport-related activities or events, and a high 52% was somewhat interested, which is still can be managed to be persuaded to joint in or at least only as spectators of a game or championship. It is left only 25% of the tourist market confirmed that there were of conventional group of tourists and not interested in anything related to sports. Hence, Sarawak needs to develop and market more and higher quality of sport tourism's attractions, activities and events in order to attract the 75% of the potential "sport tourists" and also "tourist sports" in the market.

Similar to Milne, Sutton, and McDonald (1996, cited in Shank, 1999), the survey also discovered a few factors that may motivate the tourists to be involved in the sports activities/events. A huge motivation factor stated by the respondents was the benefit of releasing their tension while playing or observing games. The second most important reason for them to participate in sports was of health and fitness well being. It is a fact that sports and exercises are very good for our healthy body. The third most reason mentioned by the respondents was the enjoyment and experience of good time during the activities/events.

To conclude the survey, the respondents were asked of their opinion whether sport tourism has a future as one of popular tourism attractions in Sarawak or not. Results from the respondents were very encouraging towards the future of sport tourism sector in Sarawak. High 76% of the survey approved that Sarawak has a potential in developing sport tourism sector, and consequently able to attract popular attention from the tourists market.

Significantly, this is because Sarawak has abundant of geographical natural resources. Most part of Sarawak is covered with tropical rainforest and natural wonders. It possesses plentiful networks of rivers, limestone caves and mountains. For that reason, the respondents pointed out that there were three types of sports they found most attractive in Sarawak, which are adventure-based sports, sea or river-based sports and golfing. Thus, it may be best for Sarawak to concentrate on expanding activities or events along the line of these sports.

CONCLUSION

Sport tourism is one of the fastest growing segments in the tourism industry. Nowadays, many nations have starting to develop sport as a major tourism product after realizing the apparent significance that had been generated by the sport industry, which can contribute to the tourism industry (Noel, 2001). There is a growing demand for active vacations that associate with sport and physical activities. Significantly, the demands and behaviors of today's travelers have gone through some considerable changes. Hence, the concept of sport tourism in the tourism industry has becoming more prominent in the last few years both as an academic field and an increasingly popular tourism product (Gibson, 1998a).

Sarawak too has started to develop and market this new tourism sector. A number of sports events and activities have been planned and staged since past years. Many sport facilities and infrastructures were built for the public. Moreover, Sarawak possesses the necessary natural resources that can accommodate various types of popular sport-related activities and events.

Interests and pursuits in sports has become one of the attractions that can motivate people to travel, both local and foreign tourists. Consequently, the sport activities and events can bring various benefits to Sarawak's economics and tourism industry. Additionally, it is reported that the sport tourism are being staged because reasons of recreation or socialization, culture or education, tourism, internal revenue generation, natural resources, agriculture, external revenue generation, and community pride or spirit (Turco & Lee, 1996).

Fundamentally, "sport tourism" can be defined as the a phenomenon where people travel away from their usual environment to be involve in either competitive or non-competitive sport-related activities/events for fun, recreation or rewards. It is also described as a special kind of leisure, which involved challenge, excitement, involvement, community building, and satisfaction (Kelly & Freysinger, 2000). Moreover, it is also interpreted as a cultural experience of the physical activity and challenge. And for the purpose of simplification, sport tourism can be classified in a number of ways. In addition, the sport tourists and their behaviors are also discussed for further understanding.

In conclusion, the survey supported the potential of Sarawak as one of the celebrated sport tourism destinations. Even though for the time being Sarawak only succeeded in attracting a small percentage of sport tourists, Sarawak still has big prospect in developing and marketing the new sector to the global tourism market. 25% of non-sport tourists admitted to be involved in sport-related activities and events during their visitation albeit their major reason going to Sarawak is sightseeing or other than related to sports. Furthermore, 75% of the survey revealed of their interest to either participate or observe sports-based activities/events. Thus, they can surely be persuaded and promoted to joint in the sport tourism activities/events coupled with desirable circumstances. Essentially, a high 76% of the survey believed sport tourism can be a popular tourist attraction in Sarawak.

Factors that Influence Japanese Outbound
Travel to Malaysia in the Contemporary Environment: An Empirical Analysis

Shaharudin Tahir[1]

Choo Sook Yee[1]
[1]Universiti Utara Malaysia
[2]Universiti Malaya

ABSTRACT

The tourism industry has been a catalyst to our nation's economic growth. The contribution to our nation's Gross Domestic Product (GDP) is undeniable. However, due to recent global unrests, the performance of this industry has since switched to a lower gear. Therefore, the Malaysian Government has put intensive effort to encourage the outbound arrivals. Japan is one of the largest tourism generating market in Malaysia, other than Asian country (Singapore, Thailand, Indonesia and Brunei). A percentage of Japanese arrival has increase from 286,940 million in 1999 to 354,563 in 2003 and the tourist receipt from this country increase by 4.0 percent in 1995 to 2000. Thus, this paper attempts to study the factors that influence Japanese outbound travel to Malaysia in the contemporary environment. We take the number of Japanese arrivals to Malaysia as a proxy. The dependent variable used are Gross Net Product (GNP), exchange rate, price of tourism and contemporary environment as a dummy variable.

INTRODUCTION

The tourism industry has been a catalyst to Malaysia's economic growth since 1990's. Being a key component of the service sector, its contribution to our nation's GDP is undeniable (Laporan Ekonomi, various years) thus it is not surprising that untiring efforts have been taken by our government in promoting the tourism industry to both local and foreigners.

Based on the statistics report from Malaysia Tourism Promotion Board, other than the ASEAN countries, namely Singapore, Thailand, Indonesia and Brunei, Japan is the largest tourist generating market in Malaysia until year 2000. Beginning from 2001, the number of japanese tourists to Malaysia has lagged behind China. (For details, please refer Table 1: Tourist Arrivals To Malaysia From Selected Market)

Table 1:Tourist Arrivals To Malaysia From Selected Market 1999 -2003

Country of Residence	January		December		
	1999	2000	2001	2002	2003
SINGAPORE	4,900,084	5,420,200	6,951,594	7,547,761	5,922,306
THAILAND	498,578	940,215	1,018,797	1,166,937	1,152,296
INDONESIA	307,373	545,051	777,449	769,128	621,651
BRUNEI	187,704	195,059	309,529	256,952	215,634
CHINA	190,851	425,246	453,246	557,647	350,597
JAPAN	286,940	455,981	397,639	354,563	213,527

Source: www.tourism.gov.my

The question is what are the factors that alter this trend? To answer this question, a study that aims to investigate factors that influence the Japanese outbound tourists to Malaysia in this contemporary environment is in time. Therefore, this paper attempts to examine the factors that influence the Japanese outbound to Malaysia. Besides it also measure the sensitivity level (elasticity) of Japanese tourists to those factors and we have included the global negative shocks such as the outbreak of SARS, Iraq War as dummy variable in this paper.

This paper is organised as follows: Part II presents the overview of japanese outbound tourists to Malaysia. This followed by the literature review. Part IV discusses about the methodology and empirical results respectively and Part V provides the conclusion and some policy implications.

OVERVIEW OF JAPANESE TOURIST TO MALAYSIA

The Japanese outbound holidays were liberalized in 1964. With the introduction of the Ten Million Programmed (10MP) by Japan's Ministry of Transport, the international outbound become popular to Japanese. Japanese representation in the international tourism market has been steadily increasing and contributed to the economic growth and level of expenditure to the country. Despite of the recent economic recession, Japanese outbound does not have much negative effect, as overseas travel has been widely popularized.

The Japanese Tourism Board Foundation reported that Japanese tourist motivation has change from for the 'sake of travel' to that of 'specific objectives'. The Japanese travelers seem to be very eager to acquire new knowledge and to enjoy adventure through overseas travel. The nature and scenery, historical sites and architecture, local cuisine and favorite foods, rest and relaxation, shopping, different experience, art galleries and museums, meet local people, water sports and knowledge are the preferences of Japanese travelers. However, demographic factors such as gender, age and marital status will have an effect on these motivation. (David, 2001)

In effort to boost the Malaysian tourism industry, the government has allocated a RM1 billion development expenditure over the next five years under the Eight Malaysia Plan, 2001-2005. An intensive promotion, advertising, campaign and information dissemination have been done to encourage more tourist travel especially from Japan. In this regard, aggressive promotional activities were carried out under the theme of "Malaysia Truly Asia" to promote the unique blend of natural beauty and a rich diversity of culture, traditions, history and lifestyles of the various ethnics in Malaysia. This is one of the motivation factors for Japanese to visit Malaysia. (Eight Malaysia Plan, 2001)

Furthermore, the Malaysian tourism product such as hill and island resort, shopping destination, thematic events, sports and recreation tourism, cruise tourism, eco-tourism, cultural and heritage tourism are attract Japanese travelers to Malaysia. The event such as Colours of Malaysia, Merdeka celebration, Festival celebration such as Hari Raya Aidiladha, Deepavali, Thaipusam, Christmas and Chinese New Year are a new experience for them. In other words, cultural curiosity would be the most influence factor for Japanese to visit Malaysia. With the rapid improvement and construction in the transportation system have provide an easier access to tourist destination. It has encouraged the tourist to travel more. Hence, "word of mouth" effect make the Japanese tourist visit Malaysia either for vacation, holiday, meeting or business travel.

Other than that, Malaysia can provide the new and unusual experience for Japanese while visiting Malaysia. This country has different culture and makes them fell escape from daily life. A multiracial nation, religion and variety of festival and food but live in harmony is one of the influence factor why Japanese visit Malaysia. It known as one of motivated factor for Japanese to have outbound holiday.

The general attitudes will have some effect on have vacation of Japanese. The studies done by David (2001) found that Japanese attitude towards taking outbound holiday is becoming more positive and overseas holiday is treated as a status symbol.

A destination's image may be based upon ideas and impressions that the prospective traveler holds about the destination and therefore may influence tourist motivation. It will be a positive image and then attract Japanese to travel or a negative image. A health concern is one of the hindering factors for Japanese travelers to Malaysia. The SARS epidemics has lower the Japanese arrival to Malaysia by 59.7 percent to only 8,706 in April 2004.

Other than that, a concern of security is a most important factor for Japanese to have vacation. It could be said that Japanese think that being abroad would be unsafe compared to staying in Japan. According terrorism problem, arrivals from Japan has drop by 49.5 percent to 13,310 in October 2001. This is because Asian country including Malaysia has been mark as terrorist place. This issue make Japanese tourist fear of flying and then reduce the number of arrivals for vacation, holiday, visiting and business trip to Malaysia.

The study found that Japanese are likely to consider "time" as a hindrance when regarding going on a holiday abroad. That may be the reason why Japanese have short stay and prefer to have package tour. The reason for this contradiction could be cultural because the Japanese tend to be workaholics and they urged to work by feeling guilty taking time off when their colleagues are working. Therefore, the Japanese tend to avoid taking holiday and find it is difficult to take holiday even though they afford to do so.

The Japanese Tourism Board have listed the hindering factors of overseas travel by Japanese which is security concerns, language concern, higher cost, food, anxiety about health, fear of flying, dislike foreign travel, cannot take time off, need to take care family, tiresome travel application procedure, do not agree with foreign custom like tipping and corrupt and overseas travel is extravagant.

LITERATURE REVIEW

Based on the previous research, we found that only a number of studies focused on Japanese arrival in Singapore and British Columbia. For example Tak (1998) investigated the Japanese tourist arrivals in British Columbia and its implication. The author used tourist arrival as a proxy for tourism demand factor of income, relative price index, exchange rate and habit persistence. By using the Ordinary Least Square technique empirical result showed that income and habit persistence were significance while exchange rate not. The empirical results also potrayed that season have some significant effect on tourism demand.

David Gilbert (2001) studied the factors of Japanese tourism demand for the United Kingdom (UK). This studied found various cultural aspects of demand as well as the constrains and the push factors that motivate the Japanese to choose outbound holiday. It also found that UK's features such as culture, language and novelty are important pull factors.

In 2002, Tak ran quite similar research as 1998 but focused on the seasonal variation of Japanese tourist arrival in Singapore. The author used the ratio-to-moving average technique to obtained the 12 seasonal indices from 1985 to 1998 and found that Japanese tourist arrivals are stable over the time.

Christina (2002) studied the Portuguese inbound international tourism demand from five countries of origin namely France, Germany, The Netherlands, Spain and UK. In her study, she examined the long run relationship between the demand for holiday visits and the variables that affect holiday travel such as income, destination prices and travel cost by using Johansen cointegration analysis.

In 2003, Song examined the demand for Hong Kong tourism by using the Ordinary Least Square (OLS) method. The studies pointed out found that the most important factors determined the demand for Hong Kong tourism are the cost of tourism in Hong Kong, income in origin countries, the cost of tourism in the competing destinations and the 'word of mouth' effect.

Lim (2004) studied the major determinants of Korean outbound travel to Australia from 1980 to 1994. The seasonal tourist arrival was computed using the ratio-to-moving average technique and found that season have some influence on outbound travel from South Korean to Australia. It was noted that the peak was on January during the Lunar New Year Holiday and the lowest was on September. Furthermore, Ordinary Least Squares (OLS) technique was used to estimate the economic tourism demand variable and found that gross net product, exchange rate and relative price are significant.

Nicholas Distains (2004) done an empirical study of German and British tourism demand for Greece by using the cointegration analysis. The model used the tourist arrivals from origin country as a proxy of the real income percapita, tourism prices, transportation cost and exchange rate. The studies found that real income percapita, tourism prices, transportation cost and exchange rate are the determinants variable of tourism demand in Greece.

DATA

Based on the literature review, we have identified five most frequently used explanatory variables in tourism demand studies. They are Gross Domestic Product of Japan (proxied by Industrial Production Index (IPI) due to unavailability of montly data), the relative tourism price (that is the ratio of Consumer Price Index (CPI) of Japan to Consumer Price Index (CPI) of Malaysia), exchange rate, global negative shocks (NS) and seasonal effect (S). Whereas the Japanese tourists arrival (Y) has been determined as our dependent variables. It is a measure of Japanese confidence level for travelling to Malaysia. Thus, the Japanese confidence level for travelling or outbound Japanese tourists to Malaysia can be summarised as follows:

Y = f(IPI, TP, ER, NS, S)

In this paper, secondary data consisting of monthly data for IPI, CPI for both countries, exchange rate, global negative shocks and seasonal effect is used. IPI, CPI, exchange rate were obtained from various issues of International Financial Statistics Bulletin. For global negative shocks data, it is obtained from World Health of Organisation. We only took the diseases or disaster outbreak month because it is very hard for us to justify the

exact time that we freed from those negative shocks. The seasonal effect data is based on the information provided by a Japanese tourist. Both variables are dummies. The study period span from 1991:1 to 2003:10.

Model

As the objectives of this paper is to measure the sensitivity level (or elasticity in economics term) of Japanese outbound tourists to Malaysia in this contemporary environment, a log-linear Ordinary Least Square (OLS) model is employed. The OLS Model is expressed as below:

$$\ln Y_t = \gamma_0 + \gamma_1 \ln IPI_t + \gamma_2 \ln TP_t + \gamma_3 \ln ER_t + \gamma_4 \ln NS_t + \gamma_5 \ln S_t + \varepsilon_t$$

where Y_t is the logarithm of Japanese tourist arrival to Malaysia at time t; $\ln IPI_t$ the logarithm of Japanese Industrial Production Index at time t; $\ln TP_t$ is the logarithm of relative tourism prices; $\ln ER_t$ is the logarithm of exchange rate (Malaysian Ringgit per Yen) at time t; $\ln NS_t$ is the logarithm of global negative shocks and $\ln S_t$ is the logarithm of the seasonal effect. ε_t is the independently distributed random error. γ_0, γ_1, γ_2, γ_3, γ_4 and γ_5 are the parameters to be estimated.

RESULTS AND ANALYSIS

From the results, it is found that the coefficient for the variable LOG(JIPI) is positive and has significant impact on the number of Japanese tourist arrivals. Taking the Japanese Industrial Production Index (IPI) as a proxy to the Japanese income level, one can see from the coefficient of approximately 6.29 that when the Japanese IPI increases by 1%, then the number of Japanese tourist arrivals to Malaysia increases by 6.29%. This implies that the Japanese tourist arrivals are income- elastic.

As for the explanatory variable LOG(TP), it has a negative coefficient of approximately 3.31 and has significant impact on the number of Japanese tourist arrivals. The ratio of Malaysia's Consumer Price Index (CPI) over Japan's CPI is utilized to represent tourism price. From its negative coefficient, it means that as the cost of tourism in Malaysia increases by 1%, the number of Japanese tourist arrivals will drop by 3.31%. The phenomenon here follows basic demand theory and is price-elastic.

The variable LOG(ER) has a coefficient of approximately –2.76 and also has a significant impact on the number of Japanese tourist arrivals. The negative impact of the Malaysian-Japanese exchange rate shows that when the exchange rate increases in favour of the Malaysian currency, then the number of Japanese tourist arrivals will decrease.

Apart from the above-mentioned three significant variables, there are 2 variables which are found to have no significant impact on the number of Japanese tourist arrivals. The first insignificant variable is a dummy of global negative shocks, which include wars, terrorism acts and deadly epidemic. The second insignificant variable is a dummy of Japan's four climatic seasons. These global negative shocks and Japanese seasons are found not to have any significant impact on the number of Japanese tourist arrivals. Malaysia, as the host country is peaceful and has not, in any way, involved itself in any wars or political instability during the period of study. There are also just a few scattered incidents of epidemic cases in both countries and thus no need for much cause of alarm.

CONCLUSIONS AND POLICY IMPLICATIONS

From the observations made by scrutinizing the results, a few policy implications are suggested. The high income level of the Japanese (where here, the Japanese IPI is taken as a proxy) tourists is a welcoming news to Malaysia, as higher income indicates that the Japanese can now spend a larger proportion of their income on tourism activities. The Malaysian government should put more effort in promoting Malaysia as a tourist destination to the Japanese. The Malaysian government should go all out to sell its culture, which has a similar Asian flavour as those of the Japanese, its all-year round of warm climate, as opposed to Japan's changing four seasons and its relatively less costly products, to attract the Japanese tourists.

The Malaysian government, especially the Ministry of Tourism, Culture and Arts should make more conscious move to ensure that the cost of tourism in Malaysia does not inflate. Hotel rates, entrance fees, souvenirs' prices and the likes, have to be monitored closely especially during peak seasons, when the number of tourists are the most.

The exchange rate plays an important role in influencing the number of Japanese tourists arrivals to the Malaysian shore. In this case, an appreciation of yen may somewhat be looked upon as favourable. This is because if the yen appreciates, it indicates an increased purchasing power of the Japanese, thus the spending on tourism may indirectly increase too.

ABSTRACT

Foreign direct investment (FDI) has been a subject of interest in research for many years since it has become an important source of private foreign capital for both developed and developing countries. The size and nature of FDI throughout the world has gone through rapid changes over the years. According to the World Investment Report (2003), the overall inward FDI stock in 2002 has reached $7.1 trillion, 10 times more than in 1980. Although the impact of FDI on economic development is debatable, there are many empirical findings that support its positive contributions. Research has shown that FDI had positive impact on domestic investment, exports and economic growth in Malaysia. Developing countries are thus, competing to attract FDI into their economy. Even in Malaysia, FDI has been an important source of private capital since domestic investment was just not enough to sustain economic growth. However, one area that remains controversial is the impact of FDI on technology transfer. Evidences are still not conclusive as to the extent of technology being transferred by Multinational Corporations (MNCs). Thus, the main objective of this paper is to re-examine the impact of FDI on technology transfer. The contribution of FDI on technology transfer is still at the adoption and initial phase of the rooting stage. However, there are isolated cases where some Malaysian companies have led the way to develop our own home grown indigenous technologies. This was obtained through linkage, training and competition effects. Bu,t this success is not substantial despite being a major location for MNCs since the 80s. More effective policies are needed to promote technology transfer by MNCs .If not, Malaysia will end up reaching a "stagnant" level and our economic growth will continuously depend on importation of foreign technology and skills.

INTRODUCTION

Foreign direct investment (FDI) has been a subject of interest in research for many years since it has become an important source of private foreign capital for both developed and developing countries. Foreign direct investment is defined as investments made for the purpose of actively controlling or acquiring property, assets or companies located in host countries (Griffin & Pustay 1998). Those firms that engage in FDI are commonly known as Multinational Corporations (MNCs) or Transnational Corporations (TNCs).

The size and nature of FDI throughout the world has gone through rapid changes over the years. According to the World Investment Report (2003), the overall inward FDI stock in 2002 has reached $7.1 trillion, 10 times more than in 1980. From this total, $4.6 trillion was held in the developed world and half of that in the United States, Britain and Germany. $2.3 trillion was held in developing countries and from this amount, close to 60% was held in countries in South, East and South-East Asia.

One factor that has contributed to its rapid growth is the rise of globalisation. The emergence of globalisation has forced many MNCs to expand their businesses into newer markets, outside their own countries. Many of these MNCs are moving to emerging and stable markets such as South East Asia and Latin America. According to World Investment Report (2003), in 2002 the world's MNCs consisted of 64,000 parent firms and 250,000 foreign affiliates which accounted for two thirds of the world trade in goods and services. Another factor that boosted the growth of FDI is the role played by the World Trade Organisation. The rapid promotion of free trade through the gradual removal of trade barriers worldwide has prompted many MNCs to expand their businesses into newer and more attractive markets.

MALAYSIA'S ECONOMIC DEVELOPMENT AND FOREIGN DIRECT INVESTMENT EXPERIENCE

Malaysia has gone through a structural transformation, from a country depending highly on mineral and agriculture commodities to one emphasising on manufacturing industry. The manufacturing sector has also gone into another round of transformation by slowly shifting from labour intensive into capital-intensive industries. This transformation was unavoidable due to the rise in labour cost experienced rapidly in the early 90s.To encourage greater investment into the manufacturing sector, the government relied heavily on FDI. Domestic investment was just not enough for Malaysia to sustain economic growth.

Therefore, FDI has been an important source of private capital for Malaysia since then. FDI also contributed enormously to Malaysia's economic development since the mid 80s. Before 1980s, a lot of FDI flowed into the primary sectors such as plantations and mining sectors. However, the recession in the mid 80s, forced the government to diversify the economy by accelerating the growth of the manufacturing sector. This was the beginning of a new era in the Malaysian economy since it began attracting huge amounts of FDI in the manufacturing sector as well.

FDI flows are shown in Table 1 below. From 1985 to 2002 there has been an upward rise in FDI flows except for 1998 and 2001. In 1998, the Malaysian economy suffered from the financial crisis and this affected the flows of FDI significantly. In 2001, the rapid slowdown in FDI flows was due to the world wide economic recession (World Investment Report 2003). However the pattern of FDI flows into Malaysia was in tandem with the world FDI flows.

Table 1: Inward FDI Flows: 1985-2002(UNCTAD, World Investment Report for Malaysia 2003, p.1)

(US$m)

	85-95	98	99	2000	2001	2002
Malaysia	2902	2714	3895	3788	554	3202
World	180,901	686,028	1,079,083	1,392,957	823,825	651,188

As an economy becomes more developed and modern, the role of the service sector becomes more imperative and essential.The services sector has thus become a dominant contributor to gross domestic product (GDP) in many developed countries such as United States, Japan, Australia and Singapore (Clemes, Arifa & Gani 2003). This phenomenon is also taking place in emerging economies such as Malaysia. In 2002, services sector contributed 45.9% to the country's GDP as compared to the manufacturing sector that contributed 30.7 % only (MITI 2003). Empirical investigation by Clemes, Arifa & Gani (2003) in ASEAN countries, found that growth of the services sector has positive influence on the manufacturing sector and vice versa. In other words, there are two-way spill over effects between the services and manufacturing sectors.

FDI in services can be seen in the financial, transportation, telecommuniucation, shared services, information technology, education, health care etc. One area getting huge attention from foreign service players is the call centre industry. A lot of foreign call centres have been establishing their base in Malaysia. According to Stephen Shepherd, Kelly Services Regional Director for Sales and Operation (Asia Pacific), Malaysia is becoming an important contact centre hub and a better choice for global companies to locate their call centres (Business Times, 26 December 2002).

The Multimedia Super Corridor (MSC), the country's test bed for the development and application of sophisticated information technology is also a host to MNCs such as DHL, Alcatel Networks, Acterna, Shell IT, British American Tobacco, Scope International -Standard Chartered (Business Times, 23 April 2002). He further reiterated that many MNCs are even relocating their call centres from Singapore and the Philippines to Malaysia. Industries that are relying heavily in the contact centre services in the country are banking, telecommunications, insurance, transportation and logistics. According to the Asian Call Centre Industry Benchmark Study in 2003, Malaysia has about 575 contact centres and is placed at par with Singapore, Thailand and Hong Kong (The Star, BizWeek 4 October 2003 p.27) .

The emergence of MNCs throughout the world has brought huge positive and negative implications on economic growth and development of many developing economies. One area that has attracted huge research is the impact of FDI on technology transfer. It is argued that MNCs bring in superior technology and help and spread this technology

to local firms via linkages and employment. However, empirical evidences are still not conclusive. It is unclear whether technology transfer really takes place effectively.

RESEARCH OBJECTIVE

Although FDI has played an effective role as a source of financing to a lot of developing countries, its impact on economic development through technology transfer is still debatable. It is therefore, the aim of this paper to examine the impact of FDI on technology transfer in selected manufacturing and service MNCs in Malaysia. Emphasis will also be given on the channels for technology transfer from FDI. The inclusion of service MNCs in this research would provide valuable insights to the extent of technology transfer taking place in the services sector currently. This sector is poised to be the next engine of growth in the future.

WHAT THEORY SAYS?

Theories explaining impact of FDI can be traced back to the work of Karl Marx who wrote on its impact on development and underdevelopment. This early view came to be known as the dependency theory of FDI (Fan 2002). This school of thought which became hugely popular in the 70s and 80s, viewed FDI by MNCs from developed countries to developing countries as harmful in the long run (Cutter , u.d). It argued that FDI brings negative consequences to developing countries in the form of profit repatriation, declining reinvestment, lack of economic spin-off, technology transfer and worsening balance of payment situation. However, not all supported this view. Hymer (1976), one of the earliest to study the behaviour of MNCs disagreed and theorized that FDI can have positive contribution on economic development.

This brings us to the industrialization theory of FDI suggested by Hymer (1976). According to Hymer, FDI by MNCs does not only involve capital inflows but also international production. Therefore, developing countries receiving FDI benefit not only in terms of capital but new technology, management skills, marketing know-how and human capital (cited in Fan 2002).

This industrialization theory of Hymer has been also employed in a lot of research on technology spillover from FDI. Blomstrom and Kokko (2002) and Markusen (1998) call it the 'knowledge capital model' (KCM). According to them, there exist technological spillovers from MNCs to host countries through their subsidiaries since they own certain technological advantage.

However, these theories have been empirically tested and the results have been highly inconsistent. The next section will discuss some of the empirical findings on the impact of FDI on technology transfer.

FOREIGN DIRECT INVESTMENT AND TECHNOLOGY TRANSFER

The literature on FDI provides a broad definition of technology transfer. Some define technology as managerial practices and production methods (Blomstrom and Kokko 1997). The impact of FDI on technology transfer can be obtained by examining its influence on local competitors and backwardly linked host country suppliers. These two channels of technology transfer are known as 1) horizontal flows to local competitors and 2) vertical flows to backwardly linked suppliers (Kumar, 1996; Blomstrom and Kokko, 1997; Keller, 2001 and Moran 2001). According to Blalock and Gertler (2004), the positive influence of MNCs on local competitors can occur through a number of ways. For example, local firms may get some knowledge from these MNCs which they can apply into their own companies. Some of the workers working in these MNCs may also end up opening their own companies in the future (Blalock and Gertler, 2004).

The empirical research on the impact of FDI on technology transfer and spillovers found contrasting results. Blomstrom and Wolff (1994) in their research found FDI to have positive influence on local firm productivity. This was also supported by Haskel, Pereira and Slaughter (2002) who found positive influence of FDI on local firm in the United Kingdom. A survey conducted by Marin and Bell (2003) on 1533 firms in Argentina found that FDI has positive significant spillovers on domestic firms. However, the positive impact only arises in domestic firms that have strong linkages with MNCs. In other words the level of influence depends on the absorptive capabilities of local firms (Marin and Bell, 2003).

Research conducted by Blalock and Gertler (2004) found positive influence of vertical technological transfer on local suppliers. Local suppliers are benefiting from the training provided by MNCs in technological related areas. This was also found in studies conducted by Macduffie and Helper (1997) who found positive contribution by Japanese automobile makers on American parts suppliers. Similarly, Lall (1980) also found that the Indian trucking industry benefiting from foreign automakers in India through backward linkages.

On the other hand, there are criticisms that local firms do not benefit in terms of technology transfer. Aitken, Harrison and Lipsey (1996) found that many MNCs are hiring away talent from local firms and this creates a brain drain. They also claim that since MNCs pay much higher than local firms, this has negative influence on local labor costs. Another study by Aitken and Harrison conducted in Venezuela in 1999 found that FDI has negative influence on local firms which are smaller and are not able to compete.

CONCEPTUAL FRAMEWORK

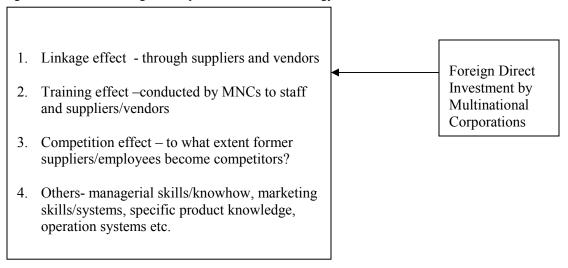
Narayanan, Yew Wah and Kooi Guan (1997) who drew their conceptual framework on the process of technology transfer from the works of Komoda (1986) and Baranson and Roark (1985) identified three major stages of technology transfer: The adoption, rooting and diffusion stage. Stage one is known as the adoption stage whereby MNCs adopt their parent companies technology locally in their affiliates in the host country.

It can be argued whether this adoption stage is sufficient since it may not guarantee much transfer of technology from the parent company to the locals. This is because in this stage the locals are merely utilizing the foreign technology. Technology transfer must therefore go beyond this level especially in Malaysia since MNCs have been present here over more than two decades.

Stage two is known as the rooting stage where the local staffs are beginning to learn on the usage of technology on their own. At this level, the usage is not confine to operation alone but includes maintenance, repair and R& D as well. The staffs are noted to have mastered the skills once they are able to carry out research independently (Narayanan, Yew Wah and Kooi Guan, 1997).

Again this rooting stage was meant more for manufacturing firms where the process of operations maintenance, repair and R & D is clearly envisaged. To what extent this can be applicable to service MNCs is yet to be seen. The last and third stage of the technology transfer continuum is the diffusion stage whereby the technology begins to be transferred or diffused to other firms within the host economy through pecuniary and technological linkages.

Another view that is similar to the technological linkage was put forward by Kokko (1992) –known as the imitation effect or demonstration effect. This view was discussed by Blalock and Gertler (2004) who reiterated that local firms can learn by simply observing and imitating MNCs. This view can be argued since it is difficult to see whether learning takes place by merely observing and imitating. Even, if learning do take place, to what extent and how much? By merely observing alone may not allow the technology to be deeply rooted to reach the secondary stage as postulated earlier. More in-depth details and knowledge of the technology warrants greater involvement of the workers which can only be obtained by closely working and learning from the MNCs. Learning can also be enhanced through training of workers.

Another view on the channels of technology transferred is the diffusion of technology transfer through vertical and horizontal linkage (Kokko, 1992; Kumar, 1996; Blomstrom and Kokko, 1997; Keller, 2001; Moran, 2001 and Blalock & Gertler, 2004). According to the horizontal linkage view, technology will be diffused or transferred to local competitors since they will be pressured to improve on the technology they currently used.This can however be argued whether this can be considered "spillover" since there may be no element of learning or it is merely through imitation or observation. However, if the competitors have gained knowledge through a working relationship with the MNCs then it is possible to consider that as technology transfer. There are also instances where employees themselves end up becoming competitors to the MNCs.


With regards to backward vertical linkage, technology spillover argument is more valid since suppliers are working together with the MNCs and may have obtained knowledge through experience and even training conducted by the MNCs.

It should be noted that MNCs can also have negative effect on competitors by forcing them out of the industry especially those that are not able to compete with the MNCs that are much stronger and larger in scale.

With that in mind, the conceptual framework that will be used for this research will concentrate and emphasise only on the "linkage effect" and "training effect" since these two are considered to be more effective in measuring the level of technology transfer. However, effort will be made to see to what extent knowledge gained by employees or suppliers through learning has led to "competition effect". Competition here will come from former employees or suppliers who are directly competiting with these MNCs by setting up their own companies. A simple schematic diagram is drawn to show the conceptual framework of this study (Figure 1). For manufacturing MNCs, technology transfer is deemed to exist if it reaches the last phase of the rooting stage and eventually the diffusion stage as postulated by Narayanan, Yew Wah and Kooi Guan (1997).

The situation gets more complicated with service MNCs since they are not involve so much with production. As such the definition of technology transfer in this study is broadened to include transfer/usage/diffusion of managerial skills/knowledge, marketing skills/systems, market knowledge, specific product knowledge, operation systems etc.

Figure 1 : Schematic Diagram: Impact of FDI on Technology Transfer

1. Linkage effect - through suppliers and vendors

2. Training effect –conducted by MNCs to staff and suppliers/vendors

3. Competition effect – to what extent former suppliers/employees become competitors?

4. Others- managerial skills/knowhow, marketing skills/systems, specific product knowledge, operation systems etc.

Foreign Direct Investment by Multinational Corporations

DATA AND METHODOLOGY

The data for this study was obtained mainly from primaryand secondary sources. To study the impact of FDI on technology transfer, interviews were conducted with senior managers of selected manufacturing and service MNCs. The selection of senior managers and the MNCs were based on convenience sampling. Six of the senior managers were from six different manufacturing MNCs scattered throughout Malaysia and another four were from different service MNCs scattered around Klang Valley, Malaysia.

The interviews conducted were highly in-depth. For those respondents located nearby, face to face interviews were conducted. For those located outside of the Klang Valley, telephone interviews were done. To ensure critical details were not overlooked, the respondents were provided with a set of questions a few days prior to the interviews. This is to allow the respondents to familiarize on the issues to be discussed and provide him/her a chance to be well prepared.

The in-depth interviews were also considered as highly structured in the sense that all the respondents were asked similar questions. However, they were allowed to elaborate and given opportunity to provide additional information/feedback if they wanted. This was done to ensure there existed consistency in the data collected and easier to analyze the opinions/facts provided during the analysis stage. Secondary data was also obtained from economic reports and newspapers where applicable.

DEMOGRAPHIC PROFILE OF THE RESPONDENTS AND THEIR RESPECTIVE MNCS

This section briefly outlines the demographic profile of the respondents and MNCs involved in the study. Table 2 and 3 depicts in detail the background information of the respondents and MNCs.

Table 2: Background of the respondents from the manufacturing multinational corporations

Respondents	Number of years experience	Current MNC	Nature of Business and R & D Location
First respondent (Senior Manager)	(12years) -has worked previously in two American and one Japanese firm in a similar environment	American This MNC was established in Malaysia in 2001	Manufacturing - labor intensive - a technology leader for fiber optics subsystems and network performance test systems -between 50 – 70 % of products are exported -R & D is done in the US -HQ
Second Respondent (Senior Engineer)	(12years) - has worked previously in an American and another Japanese firm in a similar environment	Japanese This MNC has been in Malaysia since 1973	Manufacturing -capital intensive - production of rare earth marnets, epoxy molding compounds, semiconductor silicone wafers, silicone rubber rollers, embossed carbon tapes -close to 50 % of products are exported and balance for the local market - R & D centers exist in each plant to tie them closely to each business and manufacturing division. However, core R & D activities are still based in Japan (HQ)
Third Respondent (Manager)	More than 8 years experience in this organisation	American	Manufacturing -Capital intensive -World's largest chip maker, also a leading manufacturer of computer, networking and communications products. - This MNCs design centre for handheld equipment is located in Malaysia.
Fourth Respondent (Senior Manager)	More than 15 years with this organisation	American	Manufacturing -global leader in wireless, broadband and automotive communications technologies and embedded electronic products. -capital intensive -This MNC has an R&D centre in Malaysia and designated it as a corporate design centre for cordless telephones worldwide
Fifth respondent (Senior Manager)	More than 10 years with this organisation	European	Manufacturing and Sales -capital intensive -Manufacturing of 1) Consumer products such as portable entertainment systems, home audio.video etc 2) Healthcare products 3) Semiconductors - More than 90% of the products are exported -The R & D centre is located at the HQ
Sixth respondent	10 Years	Japanese -This MNC has been in Malaysia since 1972	Manufacturing -capital intensive -Manufacturing of airconditioners - Established an R & D centre in 1991 -established technology centre in 1991 -established technical training school in 2000.

Table 3: Background of the respondents from the service multinational corporations

Respondents	Number of years experience	Current MNC	Nature of Business and R & D Location
First respondent	8 Years Established in Singapore in 1995	-Joint Venture between an American public listed company and the existing founder	Services -No R & D is done since their business is service based. However, R & D related to development of solutions and ICT technologies is outsourced or done by vendors
Second Respondent	10 years -went into hypermarket retailing in 1995	100% owned by a Hong Kong Based Company	Services - Retailing business from small scale supermarkets to hypermarkets - R & D is more related to market research and not development of products.
Third respondent	15 years	American	Services - total logistics provider
Fourth respondent	20 years	British	Services -The services provided are banking solutions and mainly related to CRM systems, work processes, use of integrated banking software and services etc.

MAIN RESULTS

This section will examine and evaluate the extent to which technology transfer by MNCs in both manufacturing firms and service industries are taking place in Malaysia.

FDI AND LINKAGE EFFECT – BY MANUFACTURING MULTINATIONAL FIRMS

Findings from the interviews conducted with the senior staff at the various manufacturing and service firms brought mixed results. All the respondents from the foreign manufacturing firms agreed that technology transfer exist at the adoption stage. The backward linkage effects exist when the manufacturing firms conduct business with their suppliers. For example, one Japanese manufacturer relies on these suppliers for spare parts, inspection equipment, raw materials, packing and packaging materials. However, for this Japanese firm, there is a tendency to rely on their own Japanese suppliers who are able to provide reliable and quality inputs according to their requirement. One reason cited for this is the difficulty for local firms to comply with their stringent terms and conditions. This practice was also found to exist in one of the American manufacturing firm.

If this is the case, then not much opportunity may exist for local suppliers to benefit in terms of technology. So, it will be difficult for technology to be deeply rooted if opportunities are not given to the locals. With regards to R & D location, four of the manufacturing firms R & D centres are located here. (Refer Table 2). For example, one of the Japanese manufacturer's has established an R & D centre, technology center and a technical training school in Malaysia to cater for their worldwide production. So, this will definitely benefit local employees sent for training at these schools and centers. Technology is therefore not only limited to the adoption stage but may also be deeply rooted into the R & D stage as well. However, rooting of technology will also depend on the absorptive capacity of the local staff employed. Having sophisticated technology alone in the R & D centre alone is not sufficient. Locals must be able to learn and absorb the technology and be able to conduct research independently.

One European manufacturing firm has done quite a bit to promote technology transfer. It is working closely with local vendors by supporting them through business ventures. For example, the 'Touch and Go' card used by commuters on the high ways in Malaysia uses a prototype technology –'contact less smart card' developed jointly by a European and local firm. The European firm also provides information and technical assistance in the development of other proto-type products. Even the 'MyKad' which uses the myfare technology, is developed jointly by a European MNC and a local partner. So, there is an element of technology transfer seen in such ventures.

This indicates that collaboration or joint ventures tend to a higher impact on technology transfer. However, this type of collaboration cannot be seen in all organizations.

Another example of technology transfer from this firm is seen in the development of ASTRO decoders that are now 100% manufactured locally. These decoders are developed by one of the largest foreign contract manufacturers – Sanmina-SCI Systems located in Penang, Malaysia. The decoders use an advanced chip technology manufactured by the European MNC located here. The transfer of technology involves not only manufacturing technology but also quality as well as test tools systems. The benefits to the locals can also be seen in terms of employment opportunities and other spillover effects arising from the use of logistics, metal, plastic and packaging materials provided by Malaysian industries.

However, it can be argued that the main technology beneficiary is Sanmina-SCI Systems which is not a local company. So, until the benefits of technology transfer are harnessed by local companies independently only then we can conclude that technology transfer is benefiting us. This is why Malaysian companies must take the initiatives to take the lead by securing major contracts rather than just becoming small time vendors. This practice was also emulated by the Japanese silicone manufacturer. 80% of the silica and 18% of the Resin used was purchased locally from foreign Japanese firms established here. It's difficult to see any backward linkage effect if local Malaysian firms are not involved at all in the supply chain. Contract manufacturing is one area where Malaysian local companies should go into so that they can collaborate with large foreign MNCs.

However, on the positive side, some of these Japanese suppliers do employ local engineers. So, this provides an opportunity to local engineers to gain some knowledge and insights into technology used. But, to what extent are these engineers going to absorb the technology used? Further examination found that unless our local engineers take the initiative to go on their own independently, only then we can say that technology transfer has reached the rooting and diffusion stage. Merely being employed in these foreign companies will only leave them at the adoption stage which is not enough for a country like Malaysia.

It was also found that the linkage effects with local companies in Japanese MNCs is limited and only confined to the supply of low value added products such as plastic and metal products in the manufacturing of air conditioners and audio equipment. The supply of high end value added products such as power circuit, audio circuit are still being controlled by the more established Japanese suppliers who may be locally and externally based. This indicates that it would be difficult for technology transfer to reach the diffusion stage if local suppliers are not given opportunities to go into production of high end value added components.

The executive from another American manufacturing MNC supported this statement. Products produced by Small and Medium Malaysian Industries (SMEs) for these MNCs are usually limited to low technology and that are nearing its end life. This is to avoid losing out valuable technological knowledge to outside parties. If this is the case, then what ever the SMEs gain is useless in the long run and will not benefit future advancement and development of knowledge. So, this indicates that the linkage effect does not generate growth of new and advance technology but limited to technology that is deemed to be nearing its end life or obsolete.

FDI AND LINKAGE EFFECT – BY SERVICE MULTINATIONAL FIRMS

It is difficult to examine the impact of technology in service MNCs since it involves intangible output. Services are known to have idiosyncratic characteristics where workers employed are more educated with higher level skills and as such are different from the manufacturing sector in attracting FDI (Erramilli and Rao 1993). Services are also different due to its intangibility, non-storability and non-transportability that make it unique in its own sense (Von Der Ruhr 2000). Most services industries such as business process outsourcing (BPO) service providers, banking and insurance, information technology and telecommunication firms are highly capital intensive and uses telecommunication and information technology to built their competitive advantage. However, some service areas such as retailing are still very much labor intensive.

From the service MNCs examined, one was a BPO service provider, one banking, one a hyper market retailer and the last one a foreign logistics provider. In the case of BPO service providers, the technology involved is basically related to Customer Relationship Management (CRM) technology such as computer telephony integration (CTI) technology. These firms have also developed special expertise in help desk, telesurveys, event management, customer support systems and knowledge management systems. From the investigation, it was found that there are minimal backward linkage effects. Most of these BPO providers rely extensively on other foreign MNCs to

supply software, networks and other solutions. For example, one of the BPO providers got their virtual private networks, multimedia service platform, and customer contact and voice portal solution from another foreign MNC that is locally based.

However, there exists employment opportunities since almost all employees are local. Then, there is also linkage with Malaysia infrastructure providers such as "Telekom" and "Tenaga National Berhad" (TNB). This is also because the telecommunication and energy sector is highly regulated by the government. Then, there are also some linkages with small time Malaysian hardware and transportation providers. The BPO service industry is still quite new and is very much ICT based. Therefore, until there are capable locals who are able to supply the technology required, it will be difficult to see greater linkage effects arising from Malaysian companies. As such, there are not much learning effects to arise from the FDI by BPO providers through linkages with local companies.

In the hyper market retailing industry, the linkage effects can be seen through backward linkage with transporters and other logistics suppliers, local banking firms and local infrastructure providers such as Telekom and TNB. In terms of the technology used, is mainly confined to retail management know-how such as inventory management control and ordering systems, the logistics warehousing systems and operation management systems. As such, not much can be gained through linkage effects since this business does not deal with sophisticated high level technology. However, greater technology effect will be experienced by the local staffs that are directly employed by these hypermarkets. This will be discussed further in the next section that examines FDI and training effects.

With regards to the logistics sector, the technology used is basically the operating systems, logistics solutions and systems, knowledge management systems, parcel tracking systems, customer relationship management and warehouse management systems. This technology or managements systems are mostly developed internally and externally. Most of the technology is emphasizing on the integration of ICT to improve delivery systems.

Where banking sector is concern, the technology is mainly confined to Customer Relationship Management (CRM) systems, work processes, use of integrated banking software and services and other banking solutions. These technologies rely extensively on the use of ICT. It was however noted that most of these banking solutions are not developed in-house but are obtained externally through outsourcing by specialists in the fields. It was found that in the banking industry outsourcing is again controlled by foreign firms based either based regionally or from the home country. Unless opportunities are given to local companies, it is difficult to see development and growth of our own local indigenous firms excelling in this area. One reason cited again is the lack of local firms capable of competing with these foreign outsourcing giants in the provision of banking technology.

These foreign firms are able to provide an array of technology solutions such as support services for core accounting, relationship management, teller and platform automation, internet banking, account aggregation, e-commerce solutions for business and consumers, business intelligence, imaging and document management. These firms act as leaders in providing leading information management systems and business process outsourcing, as well as software and systems solutions. Malaysian firms can benefit hugely by working with foreign banks. They will not only gain access to its specialized internal resources but also skilled personnel, databases and other reference materials.

FDI AND TRAINING EFFECT – MANUFACTURING MNCS

Another channel whereby technology can be transferred from MNCs to local firms is via training. This is known as 'training effects' in the literature on technology transfer. It was found that all the MNCs examined have their own internal and external training programs. These programs are meant for both employees as well as suppliers. For example, one Japanese air conditioner manufacturer has established an advanced technical training school in air conditioning technology both for the parent company and the public. This MNC is highly capital intensive and has also established its own technology centre to improve the companies precision die and mould design. Employees not only attend training but are also selected as project heads. This indicates that learning effects exist in such organisation. This shows that technology transfer has gone beyond the adoption stage ands to some extend the rooting stage. This is evident with the involvement of Malaysian engineers to spearhead repair, maintenance and R & D work in the design of the technology independently.

But this is where it ends. Malaysian engineers remain as employees and there is not much diffusion or filtering down of technology seen. Even, if these engineers leave the MNCs, they end up working with other foreign MNCs. As

such their role may still be the same. Unless these engineers end up joining Malaysian owned manufacturing firms producing their own local products, only then some amount of technology filtration may exist.

Another European MNC has also contributed to cultivate the innovative ability of locals. For technology transfer to be effective there is a need to boost the absorptive capability of locals. Thus, this European MNC came up with a young investors challenge program to cultivate and create new technology. The program offers opportunities to students to show their creativity and foresight and imagination to create new products.

Even local suppliers are required to undergo training programs. This is to ensure these local suppliers are familiar and are able to adhere to the stringent quality control requirements set by these MNCs. Most of these MNCs products are catered for the export market and therefore it must confirm to certain level of quality determined by the buyers or importers.

It was however found that one American MNC had doubled the number of design and development engineers to 500 in its Asia Design Centre in Penang. The expansion was done to support the transfer of technology to Malaysia to produce competitive trunked radio and Associations of Public Safety Comunications Officials digital communications products. This design centre hired local talents to facilitate the expansion. This indicates that there are positive training effects from these MNCs. However, the training effects are confined to learning effects and it is yet to be seen if those trained will be able to move out on their own. This again indicates that technology transfer has gone beyond the adoption stage and moved into the rooting stage. However, it was noted again that the training effect on R & D is confined to very simple non- value added activities.

In the service sector, the training effects are also positive since most service MNCs conduct in house and external training programs for their local staff. Training is provided in a variety of areas. In the Business process outsourcing business, on the job as well as in house training program is adopted. These training programs expose local workforce to international best practices and standards. It also improves the technical capacity of local solution providers that provide software and integrated business packages especially in the banking, BPO and logistics industries.

FDI AND COMPETITION EFFECT

Most MNCs in the manufacturing sector are established firms having global presence all over the world. Therefore, this gives them huge advantage to achieve economies of scale which consequently puts them well ahead of their competitors. On top of that, they possess the required resources to invest in R & D and as such are the market leaders in their respective fields. It is difficult to see much head on 'competition effect' taking place in Malaysia. It is difficult and not easy for Malaysian companies to compete with such MNCs head on unless certain privileges are given to them. In the automotive industry, our own national car assembler, 'Proton' was given a huge handicap in terms of regulating the local automotive market from established foreign players. Even with that, it is not sure if Proton can compete successfully in the open market once The Asian Free Trade Agreement (AFTA) on automotive trade begins to take place in 2005.

However, there are isolated cases where some Malaysian companies have done extremely well. For example, IC Microsystems, a local microchip design company has done well by producing 27 chip designed under its stable. The founder of this company has worked with an established semiconductor companies such as Motorola before venturing on his own. This is a classic example of competition effect taking root. Then, there are local circuit board assemblers such as Malaysian Pacific Industries and Unisem. They have established themselves quite well in the circuit board assembling industry and are currently providing its products to MNCs locally and abroad (The Star, January 19, 2004). This indicates that competition effect has taken place.

In the service industry, there should be more avenues for Malaysian companies to flourish. The service industries rely extensively on ICT technologies which are usually outsourced from established ICT suppliers locally or abroad. It is easier to imitate the services provided by service MNCs since services are relatively d difficult to protect. This should give local companiesoportunities to strike out on their own by offering similar services. In the BPO industry, local players such as SCICOM has established themselves as the leaders in the industry. This indicates again that competition effect is beginning to take place.

IMPACT OF FDI ON THE DEVELOPMENT OF OTHER SKILLS

Apart from the development of sophisticated skills, MNCs are also involved in the development and nurturing of other intangible soft skills such as use of new management methods, people skills etc. In the services sector, such skills are very essential since this sector deals with customers directly. Therefore, employment of local staff by service MNCs will definitely enhance competence and upgrade the skill level of local staff. For example, in the BPO industries, one of the factors that attracted large number of foreign BPOs into Malaysia is their exposure and experience in people skills. The latest AT Kearney's Offshore Location Attractiveness Index placed Malaysia at number three behind India and China (AT Kearney, 2004).

Similarly, in the manufacturing sector it was found that Malaysian workforce especially at the executive and management level, are exposed to various management styles practices by the American, Japanese ands European MNCs. Working with MNCs will also expose staff with international marketing skills which may be different. It may also enhance our marketing contacts worldwide.

CONCLUSION

FDI has contributed enormously to the Malaysian economy in view of its impact on employment, export led growth etc. However, the impact of FDI on generating technology transfer is still not substantial. Most technology transfer is still in the adoption and early phase of the rooting stage. It has been more than twenty years since Malaysia opened its doors to MNCs via FDI. As such, there is a need for Malaysia to go beyond these early stages of technology transfer. What we need is a leap toward the final phase of the rooting stage and begin making in roads into the last stage that is the diffusion stage.

The government should play a more proactive role rather than just provide incentives openly. There is a need to re-examine the current FDI incentives provided and ensure that these incentives are promoting the transfer of technology beyond the adoption and rooting stage. More selected incentives should be given to encourage the development of pecuniary and technological linkages.

The Federation of Malaysian Manufacturers (FMM) should play a more proactive role to ensure that more opportunities are provided to Malaysian companies especially the SMEs who can collaborate and gain from these MNCs. These SMEs should be given opportunities to go beyond producing only low value added products to high end value added products. Only then, we will be able to see greater technological linkages and pecuniary effects arising from such collaborations. Production of high end value added products by Malaysian firms will have greater economic impact on the Malaysian economy in the long run.

There is a need also to develop further the spirit of entrepreneurship among Malaysian firms which was found to be very much lacking. This was the reason for the small or very little number of SMEs venturing into production of high end value added products. Once SMEs go into production of high end value added products, this will eventually be the stepping stone towards establishing large scale manufacturing firms producing our own home grown brands. 'PENSONIC' and 'IRIS' Are two typical local home grown companies that have made the grade. IRIS technologies is a wholly owned local company that specializes in the research, design and development of smart card technology solutions and the manufacturing of smart card related products. Pensonic is the first local producer electronic home appliances engaging in the manufacturing, assembly, wholesale and trading of electronic and electronic products.

It is difficult for the government to force MNCs to support our local industries through linkages. There is a need to ensure that our SMEs are capable and can meet up to the expectations of these MNCs interms of providing inputs at low cost high quality inputs and efficient delivery commitments. If they are not able to do this, then MNCs will be reluctant to support these SMEs. The government must ensure avenues exist for SMEs in terms of financial support to upgrade themselves. Where policies to attract MNCs are concern, it must be geared to achieve a win-win situation. If this does not happen, Malaysia will end up reaching a "stagnant" level and our economic growth will continuously depend on importation of foreign technology and skills. Ultimately, there must be certain avenues created for the development and growth of our own indigenous technology.

E-mail: mohammed.yusoff@iiu.edu.my

ABSTRACT

This paper examines the structure and trends of Malaysian bilateral exports and imports and then investigates whether these bilateral exports and imports have caused Malaysian economic growth. Although the structure of Malaysia's trade has changed quite significantly over the last three decades, the direction of Malaysia's trade remains generally the same. Broadly, ASEAN, the EU, East Asia, the US and Japan continue to be the Malaysia's major trading partners. The Granger causality tests have shown that it is the bilateral imports that have caused economic growth in Malaysia rather than the bilateral exports.

INTRODUCTION

Malaysia, as an open economy, has been very much dependent on foreign trade to achieve its economic development goals. Foreign trade (exports plus imports) has accounted for a significant and rising portion of its gross domestic product (GDP) in the last three decades, indicating that international trade has been playing an important role in the development of Malaysian economy. The share of merchandise trade in GDP was 73% in 1970, increased to 172% in 1995, and increased further to 202% in 2000. If we take the share of the merchandise trade in GDP as an indicator of trade liberalization, Malaysia certainly has gone through a relatively rapid process of trade liberalization and globalization. Thus, it has become the major objective of this paper to analyze the trends in bilateral trade relations of Malaysia with her traditional major trading partners: Singapore, Japan, the United States, and the EU and her new major trading partners: ASEAN and the East Asian nations and see whether these trade relations have had contributed to the relatively rapid growth of the Malaysian economy. In particular, the decision made by Malaysia to implement the export-oriented development strategy beginning in 1980s has been the major vehicle that has transformed Malaysia from the primary commodity based economy to a more industrial based economy. As a result, Malaysia recorded an average of 8 percent economic growth for about nine years prior to the 1997 East Asian financial crisis. This financial shock had a profound impact on Malaysian economy when it registered a negative one per cent growth rate in 1998. The economy began to recover the following year.

The paper begins with an introductory remarks on bilateral trade relations, followed by a detail discussion on the directions of bilateral exports and imports between Malaysia and her major trading partners: the USA, Japan, and Singapore. The third section deals with the issue of whether exports and imports cause economic growth in the context of Malaysia, followed by sections on the methodology, empirical results and finally the conclusion.

DIRECTION OF EXPORTS AN IMPORTS

Malaysian total trade, imports plus exports, has been increasing steadily beginning at RM 9.451 billion in 1970 and increased to RM 684.729 billion by 2000. Japan, the United States, the Association of South-East Asian Nations, the European Union have been the major Malaysian trading partners which together accounted for more than 70% of Malaysia's total trade flows during the 1970–2000 period. In recent years East Asia, comprising South Korea, Hong Kong, Taiwan and China, have become increasingly important Malaysian trading partners while that of the EU has declined. Interestingly, the direction of Malaysia's trade follows closely with the sources of foreign direct investments in Malaysia, especially in the manufacturing sector, as foreign firms investing in Malaysia's manufacturing sector generally source their intermediate goods from their parent or associated companies in their home countries. Subsequently, the processed products are exported back either to their country of origin or other markets. Hence, Japan, the US, ASEAN, East Asian and the EU have been the major source of foreign direct investment in Malaysia. In 2000, the USA was the largest investor in Malaysia at 37.7 percent, followed by Japan at 14.5 percent, Singapore at 8.9 percent, Taiwan at 4.6 percent, South Korea at 3.6 percent, and Hong Kong at 1.7 percent.

Exports

There has been a tremendous increase in the Malaysia's exports during the 1970 – 2000 period. Malaysian total exports in 1970 was at RM5263 million which increased further to RM28172 million in 1980 growing at an annual rate of 43.5 percent. In 1990 the total exports was RM79646 million registering an increase of 18.3 percent per year during the 1980-1990 period. There was a resurgence of Malaysia exports in 2000 at RM373,270 million giving a growth rate of 36.7 percent in 1990-2000 period. Most of the exports went to ASEAN and the US, followed by EU and Japan. They accounted for 76% of Malaysian exports in 1970 which declined to 70% in 2000.

Individually, in 1970 ASEAN imported 25% of Malaysian exports, the EU market at 20%, Japan at18%, the US at 13%, and the East Asian market at only 6%. In 1990, ASEAN still remained the biggest market for Malaysia's exports which accounted for 29% of total exports. However, most of our exports to ASEAN are destined to Singapore. The US was in second position at 17%, followed by the EU at 15%, Japan at 16 percent and East Asia at 12%. The importance, in terms of export shares, of the US, ASEAN and East Asia as Malaysian export markets had improved over the 1971-93 period while that of the EU declined from 20% in 1970 to 14% in 2000 and similarly the exports to Japan declined from 18% in 1970 to 14% in 2000. By 1990s, East Asia became one of the major Malaysian exports markets where its share of Malaysian exports increased from a merely 6 percent in 1970 to more than 15 percent in 2000.

By country, Singapore, Japan and the US are Malaysian major export markets. They together, accounted for 53% of Malaysia's exports in 1970. In 2000, they continued to account for more than 52% of Malaysian exports. Singapore was Malaysian largest export market in 1970 and remained so in 1993, accounting for about 22% of the exports. Japan was our second largest export market in 1970; however, the position was overtaken by the US in the 1990s. In 2000 the USA import was the major importer at 21%, Singapore at 18%, Japan at 13%. The share of Malaysian exports to the rest of the world has declined from 17% in 1970 to just 4 percent in 2000.

The structure of Malaysian exports has changed substantially. In 1970s and 1980s, most of the exports were in the form of raw materials: inedible crude materials, mineral fuels, and lubricants which had decreased from 61 percent in 1970 to 57 percent in 1980. By 1990 these exports accounted for only 33 percent of the total exports while the exports of manufactured goods had begun to emerge when its share increased from 26 percent in 1970 to 55 percent in 1990. The contribution of the inedible crude materials, mineral fuels, and lubricants fell to merely 12 percent in 2000 while that of manufactured products increased to 82 percent. Although the manufactured exports have increased substantially, it has some major weaknesses in terms of its composition. Specifically, most of the manufactured exports have been in the form of intermediate manufactured goods where their shares increased from 23 percent 1970 to 49 percent in 2000. The exports of machinery and transport equipment increased from 2 percent in 1970 to 25 percent in 2000. Malaysian exports of final manufactured goods is still relatively small contributing only 8 percent of the total exports in 2000. The changes in the structure of Malaysian exports have been due to the deliberate government policy to industrialize and develop the domestic economy through the export-oriented development strategy since 1980s by diversifying and intensifying the export base and at the same time focusing on manufactured exports.

The structure of Malaysian trade with Japan has changed over the last 30 years. In particular, during 1970 – 1990 period, Malaysian exports to Japan were mainly in the form of raw materials, inedible crude materials, mineral fuels and lubricants which accounted for 68% of the total exports to Japan in 1990. But by 1990s, there has been a significant shift towards the export of machinery, such as electrical, non-electrical and electronics, and transport equipment and as well as final manufactured goods. Thus in 2000 Malaysian exports of raw materials to Japan was only at 38 percent compared to 59 percent of machinery and transport equipment and final manufactured goods in the same period.

Similarly, Malaysian exports to the US were comprised mainly of raw materials and intermediate manufactured goods in 1970s, which accounted for 93% of the total exports in 1970 but declined to 59 percent in 1980. As foreign direct investment from the US in the electrical and electronics sector increased, the structure of Malaysian exports to the US has also changed accordingly. Specifically, Malaysian exports of machinery and transport equipment increased dramatically from a negligible amount in 1970 to 31 percent in 1980 and by 2000 it had increased to 78 percent. The exports of final manufactured goods also increased from just 2 percent in 1970 to 13 percent in 2000.

Although Malaysian exports to Singapore follows the same patterns as Japan and the USA, generally they are quite diversified resembling the Malaysian export structure. This is not surprising as Malaysia has been using Singapore to export her products since Singapore has been the major entreport port in the region. Therefore Malaysian exports to Singapore are mainly for re-export. Thus in 1970's, Malaysian exports to Singapore were

mainly food, beverages, tobacco and inedible raw materials accounting for 87 percent of exports in 1970 and 81 percent in 1980. By 1990s most of Malaysian exports are in the form of machinery and transport equipment where they accounted for 44 percent of Malaysian exports to Singapore in 1990 which increased further to 73 percent in 2000.

Imports

The major sources of Malaysian imports have been the EU, ASEAN, the US, Japan and East Asia each accounting for 23 percent, 23 percent, 9 percent, 17 percent, and 10 percent respectively in1970. Since then the Malaysian imports from EU have started to decline to 16 percent in 1980 and decreased further to 11 percent in 2000 mainly due to the fall of thr imports from the UK. The share of imports from ASEAN remained steady at about 23 percent during the same period. Malaysia began to source more imports from the US and Japan in 1970s. The share of imports from the US increased from 9% in 1970 to 17% in 1990 and remained at the same level in 2000. Malaysian imports from Japan was 17% of its total imports in 1970 but increased to 24 percent in 1990 and remained steady at about 21 percent 1990s. For East Asia: Taiwan, South Korea, China, and Hong Kong have become about equally important sources of Malaysian imports. As of 2000, Japan was the most important sources of Malaysian imports, followed by the USA, and Singapore.

In early 1980s Malaysia had begun her export-oriented development strategy focusing on the exports of manufactures. As she does not have abundant in raw materials and capital goods, Malaysia has to import more of the intermediate manufactured goods and the machinery and equipment from abroad. In 1970, Malaysia imported almost an equal proportion of food, beverages, tobacco, and fats at 21 percent; inedible crude materials, mineral fuels, and lubricants at 20 percent; intermediate manufactured goods at 25 percent; and machinery and transport equipment at 28 percent.

Japan has been one of the major sources of Malaysian imports. The structure of the imports from Japan has remained more or less the same where the intermediate manufactured goods and machinery and transport equipment accounted for more than 90% of the total imports over the 1970 – 2000 period. Nevertheless, there has been a significant shift from the import of intermediate manufactured goods towards the import of machinery and transport equipment. As a result, the share of intermediate manufactured goods imported fell from 49% in 1970 to 23% in 1993, while that of machinery and transport equipment rose from 42% to 68% in the same period. Most of the imports were intermediate manufactured goods and machinery and transport equipment which accounted for 91 percent of the imports in 1970. Beginning in 1980s, the imports of intermediate manufactured goods have begun to decline while that of machinery and equipment have started to increase. And by 2000, the imports of intermediate manufactured goods fell to 21 percent while that of machinery and equipment rose to 70 percent.

The structure of imports from Singapore has been quite diversified. The food, beverages, tobacco, inedible crude material and intermediate manufactured goods accounted for 78% of the imports in 1970. Beginning in 1990, there was a shift to import more of machinery and transport equipment accounted for 40 percent of the total imports from Singapore. Malaysian imports from Singapore are mainly raw materials and machinery and transport equipment. The imports of raw materials have been in the downward trends while that of machinery and equipment are in the upward trends. In 1970 Malaysia imported 32 percent of inedible crude materials, mineral fuels and lubricants, 26 percent intermediate goods and only 4 percent of machinery and transport equipment; by 2000 these have changed to 18 percent, 12 percent, and 61 percent respectively. In 1970 Malaysia also imported substantial amount of food, beverages, tobacco, oils and fats at 20 percent and final manufactured goods at 8 percent; by 2000 the import of these goods fell markedly and settled down at 1 percent and 5 percent respectively.

The United States has also been an important source of Malaysian imports, notably in intermediate manufactured goods and machinery and transport equipment. The imports of intermediate manufactured goods had declined from 16 percent in 1970 to 9 percent in 2000 while that of transport and equipment increased from 59 percent to 76 percent in the same period. The imports from the USA were more diversified. In 1970, the import of food, beverages and tobacco, intermediate manufactured goods and machinery and transport equipment accounted for close to 90 percent of the total imports to Malaysia, with the latter forming the largest portion of imports at 59 percent. During the last 30 years, machinery and transport equipment remained the largest import category from the US and its proportion had increased from 59 percent in 1970 to 76 percent in 2000, reflecting mainly the increase in the imports of thermionic valves for the electronic industry.

EXPORTS, IMPORTS AND ECONOMIC GROWTH

This section discusses the hypothesis of export-led growth which suggests that export growth is an important determinant of the production and employment growth of an economy. It is argued that the export growth, through its foreign trade multiplier effect, results in an expansion of production and employment. Furthermore, the foreign exchange earnings generated by the export expansion can be then utilized to import more capital goods to help increase the domestic production capacity. The production and export expansion will allow the exportable sector to experience economies of scale and the use of more efficient technology. All these suggest that there exist causal relationships between imports, exports and economic growth. In order to test for the existence of a long-run or trend relationship among economic growth and export growth and import growth, the cointegration approach developed by Engle and Granger(1987), Johansen(1988) and Stock and Watson (1988) is employed in this study. To ward this end, we analyze quarterly data of Malaysia, using the multivariate cointegration technique proposed by Johansen to test for a long-run relationship between economic, export and import growth.

Empirical studies on the export growth – economic growth relationship uses either country cross-section data or time series data for a single country such as Jung and Marshall(1985) and Marin(1992). Country cross-sections studies tend to suggest that there is a strong relationship between economic and export growth rates. There are three possible relationships between exports and economic growth could be examined, namely the export-led growth, growth-driven exports, and the two-way causal relationships, termed as feedback. Studies on export-led growth by Michaely(1977), Feder(1982), Marin(1992), Thornton(1996) suggest that countries exporting a large proportion of their output tend to grow faster than others. The export expansion results in production expansion and therefore has the ability to create spin-off effects with the other sectors of the economy through the technological spillovers and other externalities. Models by Grossman and Helpman(1991), Rivera-Batiz and Romer(1991), Romer(1990) suggest that the expansion of international trade increases the number of specialized inputs which then causes economic growth as the domestic economies become more open to international trade.

A number of economists question the export-led growth hypothesis. Specifically, Bhagwati (1988) argues that an increase in economic growth may also lead to trade expansion. Furthermore an increase in exports could be due to the reduced in protectionism. Thus, there is a possibility of a two-way causal relationship between growth and trade. Bhagwati(1988) argues that an increase in trade produces more income which then facilitates more trade. This possibility has also been pointed out by Grossman and Helpman (1991) in their models of north-south trade. Before the financial crisis of 1997, the Malaysian economy grew quite rapidly and some argue that that was because of the success of the Malaysian export-oriented development strategy. But studies on the export-led growth(ELG) suggest mixed results on Malaysia. Dodaro(1993) finds that export growth has contributed negatively to the Malaysian economic development. Bahmani and Alse (1993) concluded there is no long-run relationship between export growth and economic growth in Malaysia. But to the contrary, Doraisamy(1996) finds a bidirectional causality between export growth and economic development. A recent study by Yousif(1999) supports the ELG hypothesis.

METHODOLOGY

The issue as to whether export growth cause economic growth or economic growth causes export growth or whether a bidirectional relationship exists between export growth and economic growth should be verified empirically. This study begins by analysing the integration properties of the data. In order to investigate the stationarity properties of the data, a univariate analysis of each of the time series: real GDP represented by the industrial production index, real exports, and real imports is carried out by testing for the presence of a unit root using the familiar Augmented Dickey-Fuller (ADF) test, Dickey and Fuller(1979) and Phillips-Peron test, Phillips and Perron (1988).

If all or most of the variables have unit roots, then the likelihood ratio test is used to find out the number of cointegrating vectors. Therefore, if there is one or more than one co-integrating vectors, then there exist the long-run combination among the variables, even though they may drift apart in the short run. We shall employ the Johansen (1988, 1991) and Johansen and Juselius (1990) approach to test the cointegration among the variables in the model. If the variables are cointegrated, the the error-correction model(ECM) will be estimated to investigate the long-run and short-run dynamic relationships of the variables in the model. The error-correction terms(ECTs) are derived from the cointegrating vectors found through Johansen's multivariate cointegration test procedure. The ECM is then used as another channel to test Granger causality.

Following Engle and Granger (1987), the error-correction model (ECM) for the *i*-th country can be written as:

$$\Delta YM_t = \alpha_{0i} + \lambda_i\, ECM_{it-1} + \sum_{j=1}^{k} \alpha_i \Delta X_{it-j} + \sum_{j=1}^{k} \beta_i \Delta YF_{it-j} + \sum_{j=1}^{k} \delta_i \Delta M_{it-j} + \varepsilon_{it}$$

where Δ is the first-difference operator, YM is the domestic(Malaysia) income, X_i is the Malaysian exports to trading partner i, M_i is the Malaysian imports from i-th trading partner, YF_i is the income of the i-th trading partner, k represents the number of lags of the explanatory variables, ECM_i is the error-correction term generated from the Johansen multivariable process and ε_i is the disturbance term, i=USA, Japan, and Singapore. All the variables are in log transformed. The t-test is used to ascertain the significance of the variables in the short-run while the coefficient of the error correction term captures the short-run effects of the long-run dynamics. Since the variables are cointegrated, in the short run the deviations from this long-run equilibrium will feed back in the changes of the dependent variable forcing the movement of the variables towards the long-run equilibrium. Thus, the coefficient of the lagged error-correction term is a short-run adjustment coefficient representing the proportion by which the long-run disequilibrium in the dependent variable is being corrected in each period.

Sources of Data

In this study, the quarterly data were collected from Quarterly Bulletin of Bank Negara Malaysia and International Financial Statistics, IMF over the period 1974:1 to 2001:4. The data are the industrial production indices of Malaysia, the USA, Singapore, Malaysia; Malaysia's real exports to and real imports from the USA, Japan, and Singapore.

EMPIRICAL RESULTS AND DISCUSSION

In this section we shall discuss the results of the unit root test, cointegration test, and Granger-causality test. The lags for the unit root test are set to 4 quarters as suggested by the Akaike Information Criteria, AIC. The lag length for the ADF tests was selected to ensure that the residuals are white noise. The estimated ADF and PP statistics against the corresponding critical values reveal that the null hypothesis of unit root of the variables on level cannot be rejected at the 5% level of significance. This implies that the variables are non-stationary on levels. But the ADF and PP tests using the first difference of the variables indicate that these test-statistics are individually significant at the 1% level suggesting that the variables are stationary on first difference, that is each of the   series is integrated of order one.

The results of the Johansen cointegration test and the normalized estimates of the eigenvectors are reported in Table 1. The lag length of the level VAR system was determined by minimizing the Akaike Information Criterion, AIC. The null hypotheses of non-cointegration are rejected, suggesting that at least one cointegrating vector exists in each of the countries. The USA cointegration equation suggests that only the US income influences Malaysian income in the long run where it is significant at I percent level, while the exports and imports are not, although they all show the correct signs. In the case of Japan only the Japanese imports from Malaysia determines the Malaysian income where it is significant at 1 percent level, while Japanese income and exports to Malaysia are not significant. The cointegration equation of Singapore indicates that both Malaysian exports to Singapore and Singapore's income are significant at 5 percent level, while Singapore exports to Malaysia is insignificant.

Granger-Causality

The Granger Causality tests for Singapore, the United States, and Japan are given in Tables 2, 3, and 4. Generally, the results are not that encouraging. Specifically, in every case it is found that Malaysian exports to her traditional trading partners do not cause economic growth in Malaysia. But in all cases, it is found that it is the imports from the major trading partners that seem to cause economic growth in Malaysia. Furthermore, there is little statistical evidence to suggest that the US, Japan, of Singapore economic activities affect the performance of Malaysian economy.

Notes: * significant at 5 % level; ** significant at 1 % level, figures in parentheses are the standard errors.

In the case of Singapore, the results are somewhat interesting. In particular, the Malaysian imports from Singapore causes an increase in Malaysian income and the increase in imports from Singapore also causes an increase in Malaysian exports to Singapore. There is no statistical evidence to suggest that Malaysian exports to Singapore causes the Malaysian income to rise, but Malaysian exports have caused the imports from Singapore to increase. Thus, there exists a bidirectional relationship between Malaysian exports to and import from Singapore. The impact of an increase in Malaysian exports to Singapore on Malaysian income is rather indirect; that is an increase in exports to Singapore causes the imports from Singapore to rise, and this increases Malaysian income. Furthermore, an increase in Singapore economic activities causes Malaysian imports from Singapore to rise and consequently causes Malaysian economic activities to rise.

In the case of the United States, the results are less interesting. Both Malaysian imports from the US and the US income Granger-cause Malaysian income, but the impacts are rather weak since they are significant only at 6 percent level.

The results also suggest that the Japanese income or economic activities have significant impact on the performance of Malaysian economy. Specifically, Japanese exports to Malaysia causes Malaysian income to increase, while Japanese income cause both Malaysian exports to Japan and imports from Japan to increase. But again there is no direct link between Malaysian income and Malaysian exports to Japan.

CONCLUSION

Though the structure of Malaysia's trade has changed fairly significantly over the last three decades, the direction of Malaysia's trade remains more or less the same. ASEAN, the EU, East Asia, the US and Japan continue to be Malaysia's major trading partners. Nevertheless, their relative importance as Malaysia's trading partners has changed. The most significant is the declining importance of the EU due to the slowdown in trade flows with the UK, Malaysian former colonial master. On the other hand, trade with the US and East Asia have strengthened, leading to their rising market shares in Malaysia's external trade.

The results of Granger-causality tests suggest that there is no direct causal links between Malaysian exports and economic growth. Japanese income unidirectionally causes Malaysian exports but the evidence does not indicate that the exports causes domestic income. On the other hand Malaysian imports from Japan causes Malaysian income. In the case of the United States both of the United States exports to Malaysia and Malaysian imports from the United States cause Malaysian domestic activities but they are significant only at 6 percent level. The results for Singapore indicate that Malaysian exports to Singapore causes the imports from Singapore to increase and this increases Malaysian domestic activities but the causality between exports and imports is bidirectional.

ABSTRACT

The focus of this paper is to highlight and provide an empirical investigation of the impact for the first five years period after the implementation of TRIPS agreement. This study used a cross-country data for the mixed periods (1996-2000) to see of the impact of selected designed institutional factor viz. patent protection and domestic market conditions and the intensity of research and development (R&D) activity on the inflow of foreign direct investment (FDI). Using the cross country data analysis for the selected 56 countries, we found that with stronger patent protection and R&D concentration ratio for the sample selected countries is one of the significant factors affecting FDI inflow. The investment in FDI is rather mixed in view of countries development level, IP strength, R&D intensity and domestic market transparency. For developed countries, all the simple effect two way interaction contribute significantly to the FDI. We conclude with three potential options; (1) *Move towards to provide more efficient IP protections,* (2) *Intensifying technological research and development program;* and (3) *Working towards combating illegal activity.* For this last option, developing countries were still behind due to insufficiency of intellectual property law enforcements.

INTRODUCTION

Intellectual property - IP (or human creation or creativity) in his old fashion protected under Paris Convention, 1883 which consist of two main property namely industrial property and copyright, administered by the World Intellectual Property Organization (WIPO). The objective of WIPO of is to promote the protection of intellectual property among members throughout the world. Started as early as 19th century, IP protection nowadays, entering even more challenging global phase when both WIPO and World Trade Organization (WTO)[1] has agreed to include such property as a trading items (considered as a product) via Trade Related Aspect on Intellectual Property Protections (TRIPS) agreement effectively came into force in January 1 1996[2]. Under such comprehensive agreement, country members are given one year (for developed countries) up to four years (developing countries) to comply and upgrade (i.e. Article 65.1 and Article 65.2) their existing IP law and practices in order to meet the ceiling standard of protection requirement [3].

Due to the rapid growth for both creations and trade activity involving inventions and innovations product (or process) from developed (North) to developing countries (South), the impact of TRIPS agreement during and after the transition periods became an important issues to be examine, though it is too early to do so.

---

[1] WTO was concluded in April 14, 1994 (of the Marrakesh agreement) and entered into force on January 1, 1995.
[2] The agreement between WTO and WIPO was concluded in Geneva on December 22, 1995, and entered into force on January 1, 1996 [Article 5, WIPO-WTO Agreement 1995]
[3] For developed countries, the transitions periods ended on 31 December 1996 and for developing countries member the transitions periods ended on 31 December 1999. However with subject to Article 1 of TRIPS agreement, members may or may not obliged to implement in their law more extensive protection than is required as long as such protection does not contravene the provisions of the agreement.

Policymakers in each countries member continuously put forward their effort to formulate effective and efficient strategy and practices not only to comply for but more importantly to reap such benefits that had been proved from the industrialized countries experiences. As highlighted under Article 7 of the (TRIPS) agreement:

> *"The promotional of technological innovation and transfer and dissemination of technology will hopefully benefit such users and producers so as to reach the conducive social and economic welfare with balanced rights and obligation."*
> *(WIPO: 1996, Pp.18)*

To balance the benefits between the North (developed) and South (least-developed one) provision under the Article 66.1 and 66.2[4] of the agreement had been further specified and specifically for South regions to create a sound and viable technological base with subject to incentives provided by the North regions (developed) members.

The paper is organized as follow. Section 2 discusses the objectives and methodology used in the paper and review previous literatures on the matter under study. Section 3 scrutinizes the issues of industrial development progress as an impact of advancement of IPR through foreign direct investment (FDI). Section 4 critically assesses the theoretical framework used in the analysis. Section 5 will draw the analysis, which contains the empirical results and concluded with Section 6.

OBJECTIVES OF STUDY

This paper interested to study the importance of economic function of the patent protections for the dynamic performance of the cross-country economy. The analysis involving random observation started from 1996 up to the year of 2000.

The objective of this paper is to analyze the significance impact (though it is too early to provide conclusive evidence) of IP protection to FDI inflow for selected cross-countries samples from the stipulated time periods under the TRIPS agreements. Two designed institutional factors opted i.e. patent protection index (IPRS) and black market index (BMI). The IPRS is an indicator for levels of protection (i.e. standard protection derived from the book of law) to the inventors of newly invented products or process with limited[5] monopoly powers to exercise his/her rights. The BMI is view as the transparency of the domestic markets conditions. If, for certain countries, the black market activity (illegal transaction) exists in the economy, the incentives and benefits left to the investor are violated due to high implementation cost. The R&D intensity included in the analysis as to identify on what consequences might turn up to FDI investment.

The interaction between explanatory variable will also be examined. The interaction between variables in the analysis will give different view of what level of FDI might exist given a country level of protection, ceteris paribus. This motivates us to examine on how the interactions of those variables might associate each other in order to achieve the momentum to speed up the economic development process.

An analysis involving developing nations will also be conducted to assess the implications of such factors in viewing the FDI impact given sets of determinants. The advantage of strengthening IP level especially for developing nations, given the existence of other factor will give different options and approach in promoting and enhancing their foreign investment policies and preparation that need to be taken if these nations get in touch with desired certain level of development.

METHODOLOGY

In this research, combinations of descriptive analysis will be used to analyze the data. Since set of data used is cross sectional obtained from secondary sources include sets of cross countries variables, therefore regression analysis technique is derived with several extension model to capture the behaviour of independent variables through extended regression analysis. The regression model will be fine-tuned to detect and correct the existence of multicollinearity, heteroscedasticity and autocorrelation (if any) as well as functional problem as a

---

[4] Article 66 of TRIPS agreement is complemented by Article 65 with subject to the provision of Article 3, 4 and 5 in order for these countries to fully comply with the agreements.

[5] Granted patent holders are given limited monopoly power to exercise their rights. As a standard protection, according to the TRIPS agreement under Article 33 with subject to exclusive rights conferred which clearly stated under Article 28. For the purposes of this study the standard clause of limited powers which was designed by Park and Ginarte (1997) were mainly referred to years of protection i.e 20 years upon filing the application and 17 years upon granted.

pre-requisite to the classical assumptions. An extension of the model is to assess the possibility of different development level using several construct dummy variables.

DATA AND MEASUREMENT

This estimation involving cross-country data for 56 selected countries. The selection of countries is limited by the available information for the selected variables. The data are obtained from various sources. The data for inflow of FDI were obtained from United Nation Conference on Trade and Development (UNCTAD, 2003). All data quoted in $US million Dollars for the respective reported years. The R&D expenditure is obtained from UNESCO Institutes of Statistic which are also available online. The R&D expenditure data are quoted as a percentage of Gross National Product (GNP) for each country set. The patent protections index value for the year of 2000 is obtained from Park and Wagh (2002)[6]. Since the selected countries taking periods from 1996 up to the year 2000, therefore indices for the year 1996, 1997, 1998 and 1999 for each country sample were calculated using the same framework used by the authors. The black market index is obtained from Gwartney et.al, Economic Freedom of the World (various issues).

PREVIOUS LITERATURES

Previous studies on IP protection to economic growth are contentious. An argument among researchers, academicians and policymakers to the previous empirical work has given rooms for other researcher to uncover the new evidence especially issues involving cost and benefits of providing strong IP framework (Rapp and Rozek, 1990). These sections will provide a context for analysis and as a platform to identify the impact for the issues that cover in this paper. The literatures developed in this paper vary in various related topics and discussions. The main concern is to identify the mechanisms process provided by the stronger IP framework given other factors remained intact.

Historically, the speed up process vary from country to country due to different economic development progress[7], level of new technological and/or knowledge stock[8], accessibility of infrastructure, availability and dissemination of information and other economic environment including international trade policy, political stability and even culture. In viewing the mechanisms, the existing literature constructed as follows: <u>Firstly,</u> the literature shows the evidence on how the IPRs affect economic growth and productivity. <u>Secondly,</u> identified the possible benefits of such process as a result of strengthening the IP framework and <u>finally,</u> the discussion proceeds with some evidence from other relevant perspectives (i.e positive and normative) including economic transparency and cultures differences.

The ultimate documented agreement (TRIPS-Article 7; WIPO, 1996) gave an opportunity for South (developing nations) to reap the benefits, which has already experienced from the North (developed nations). The details of the provision critically discussed by among other, Paras Gorasia (2002), Ganguli (1998), McCalman (2001) and Lall (2003).

Gould and Gruben (1996) found that stronger patent protection significantly affect the economic growth especially in an open economies, which denotes by the interaction between patent protection and dummy trade policy variables (i.e represent by black market premium, real exchange rate distortion and comprehensive trade index).

Eaton and Kortum (1996) found the evidence from 19 sample set of OECD countries. Each of the OECD countries in their analysis share the same rate of relative productivity which induced from the innovation activity and emphasis that half of the growth in the selected OECD countries in the sample set were driven by the innovation activity originated from the United States, Germany and Japan. Moreover, Maskus and McDaniel (1999), also found the same conclusion where the technology diffusion through the post war Japanese patent

[6] A detail of the original work by Park and Ginarte (1997) is based on the index calculated from five main categories of patents book of law. (1) Extent of coverage, (2) membership in international patent agreements, (3) provisions for loss of protection, (4) enforcement mechanism and (5) duration of protections. However, according to Park and Ginarte (1997), the indexes are sensitive to weighting. (Pp. 288).

[7] Different economic development progress can be viewed according to classification made by United Nation (i.e. categories divided into groups of developed and developing countries) or classification made by The World Bank (i.e. countries groups into level of income categories)

[8] Also refer as human capital stock.

protection system had significantly affect the total factor productivity (TFP) of Japanese economy through the innovation process.

Kwan and Lai (2003) however provide the extended analysis (i.e. using dynamic general equilibrium) on the impact of IP to economic growth and welfare to the US economy. Their analysis found that the welfare loss were substantial (i.e. involving the current consumption) as a results of under-investment in R&D due to under-protection of IPRs.

The process of economic growth induced by many factors, and among the researcher, they believes that the development process were driven mostly by the process of technology ownership (among others) brought from the FDI process. However the technology ownership will only exists when IP framework strongly enforced in such countries.

THE ROLE OF FDI IN INDUSTRIAL DEVELOPMENT

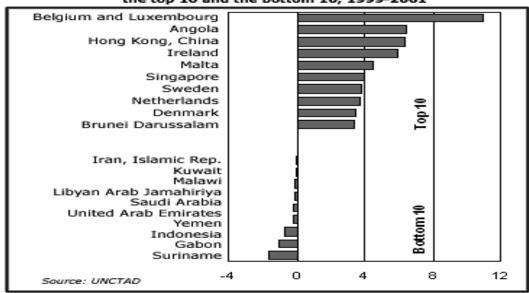
Countries Industrial development, among other things, closely linked to the ability of an industry to produce output through internal (domestic) and external (foreign) investment sources through an attractive (or effective) investment policies. Report from United Nations Conference on Trade and Development (UNCTAD, 2003), it is clear, at least four possibilities or situation when comparing countries FDI performance (inward) and potential.


Table 1: Matrix of Inward FDI

	HIGH FDI PERFORMANCE	LOW FDI PERFORMANCE
HIGH FDI POTENTIAL	Front-runners (I)	Below potential (II)
LOW FDI POTENTIAL	Above potential (III)	Under-performers (IV)

Source: UNCTAD (2003)Notes: FDI performance and FDI potential are measured by an index and each cell value measured by taking various factors.

Table 2:

The UNCTAD Inward FDI Performance Index, by host economy : the top 10 and the bottom 10, 1999–2001

By taking two extreme comparisons, group (I) and (IV), i.e. countries with "high FDI performance" and "High FDI potential", most of the countries included in group (i) are newly industrializing and advanced transition economies, however the latter [group (IV)] mainly consists of poor economies (including all South Asian economies, poor and least developed countries, along with Turkey).

Benchmark made by the UNCTAD taking periods 1999-2001(Table 2), found that for Bottom 10 group, the inward performance index are very small or almost zero to negative (with score index between -1.613 and -0.016, except for Iran, Islamic Republic, 0.001)
Studies found that level of FDI (shortly investment) received by host countries in developing and least-developed region are determined by three factors (or advantages which direct investment should have by the institutions) namely ownership, locations and internationalizations (Dunning, 1980)

An ownership advantage is described by the advantage which firm has over its rivals in terms of intellectual property ownership (i.e trademarks or brand name and patent) or knowledge or marketing. Locations advantage however described by the advantage derived from the host country's comparative advantage or its transaction cost including the absence of a tariff on the product if produced in the host country. Internationalizations factors are the value judgment or consequences approach on what types of investment package should be channeled to the host country.

Borensztein et.al (1998) which was inspired by the endogenous growth model through the technological progress of capital deepening process has found the evidence on how FDI from industrial countries become an important vehicle for developing countries to achieve better foundation to lift up economic growth conditionally to the human capital stock avail by the host countries. Markusen and Venables (1999) however found some linkages (forward and backward) on how FDI largely become a catalyst for local industrial development. The research is based on the analysis of input-output framework.

ATTRACTING FDI: THE ROLE OF GOVERNMENT

Rapid economic developments over the past three decades change view of many developing and least-developed countries to the importance of FDI through an aggressive campaign of investment promotions to attract investment. According to Dean (2000), the successful story of Singapore in the early 70's through an aggressive campaign to attract foreign multinational company (especially from United States of America) has changed their economic landscape from least resources country to Newly Industrialized Economies (NIEs[9]). The important role of FDI to industrial development in developing country also changed Botswana[10] economic outlook from a least developed country status to middle-income country[11] (UNCTAD, 2003).

However, the important role of FDI to industrial development much depends on countries policies reforms (Wint and William, 2002) and other internal factors as viewed by Gastanga et.al (1998), Smarzynska and Wei (2000), Janeba (2001) and Wei and Wu (2001). Gastanga et.al (1998) examines the issues from the perspective of host country reform specifically involving the majority of less-developed countries. By applying the perspective of the "eclectic theory"[12] for international investment, the authors found that host country policies are capable of influence FDI inflows primarily through the advantages of location aspect in the host country. The authors used multivariate analysis using pure cross-section and panel data fixed effect estimation for 49 less-developed countries over 1970-95 involving two different sources of FDI data with two different measures of capital control. However, the results from both analyses were slightly different due to complementary between various elements of investment climate and this might be overstates the effectiveness of individual policy reforms.

Wint and Williams (2002) in view of the role of government in developing countries in attracting FDI through promotional activities found that level of development has become a significant factor. They emphasize that functional policy (rather than selective) especially to developing to promote investment activities. However, due to data limitations their empirical analysis does not provide such support.

---

[9] NIEs include Singapore, Hong Kong, South Korea and Taiwan. These group also known as Asian Tigers among economist.

[10] Botswana has never had a foreign law but has welcomed FDI in almost all area.

[11] The country income classification s produced by World Bank in July 2003 and effectively until July 2004. For details income country classification visit: www.worldbank.org

[12] The "eclectic theory" which was used by the authors is divided into three sets of advantages which direct investment should have over the other institutional mechanisms available to the firm for satisfying the needs of its customers at home and abroad. The three factors namely ownership, location and internationalization (i.e. OLI) which was pioneered by Dunning (1981)

INTEGRAL PART OF ROLE OF RESEARCH AND DEVELOPMENT (R&D) AND TECHNOLOGICAL TRANSFER (TT)

Research and Development activity (shortly R&D) or innovation oriented efforts are becoming a major engine for technological progress (Coe and Helpman, 1995). Source of innovation activity could be from domestic R&D capital and also from foreign R&D capital. The R&D activity is an integral part of level of technological transfer through internalize of FDI (UNCTAD, 2003). The rapid R&D activity as a consequence of rapid FDI, viewed as a <u>pull factors</u> for investors to invest in high technology industry through an attractive package (i.e licensing and other contract arrangements and strategic alliances between local and foreign firms). For the end result the TT effect will definitely spillover into the industries and extensively assimilates to promote sound and viable economic growth in the host countries.

There are at least three (i.e interrelated) channels or source of TT. Firstly, licensing (Eaton and Kortum, 1996), secondly through FDI (Borensztein, De Gregorio and Lee, 1998) and last but not least, international trade (Markusen and Venables, 1999 and Markusen, 2000). Researcher like Coe and Helpman (1995), Gustavson et.al (1999), Serapio and Dalton (1999), Bayoumi et.al (1999), Takalo and Kanniainen (2000), Wakelin (2001), Fosfuri et.al (2001), and Varsakelis (2001) has their own view on the issues. Coe and Helpman (1995) believe R&D is one of the major engines for growth. However the presence of local externalities through local R&D stock (Gustavson et.al, 1999) is one of the determinant factors for competitiveness as well as stock of knowledge from total R&D in the domestic industry. The importance of supply factors in influencing a company's foreign investment decision in R&D is conducted by Serapio and Dalton (1999) and the importance of R&D spending, R&D spillover and trade in boosting growth in industrial and developing countries (Bayoumi et. al, 1999) had proved to increase total factor productivity.

Study conducted by Takalo and Kanniainen (2000) found that a commitments to an R&D project are capable to create future option for patenting and market introduction that influence in promoting productivity growth when firm's own R&D expenditure taking into account (Wakelin, 2001). Varsakelis (2001) however found that R&D investments are significantly determined by national culture in an open economic region with strong patent protection. Up to this point, most studies relating the FDI to R&D spillover, among other things, are interconnected with other various factors. As noted by UNCTAD (2003) in his World Investment Report 2003 believed that FDI is still become an important channel for TT even though global FDI flow for all region in 2002 were recorded decline.

The ambiguities in the empirical analysis concerning standardizing patent protection among nations provide some room and opportunities for researchers, academicians and policymakers to continuously investigate other factors as to further developed and enhance the analysis. International treaties (i.e TRIPS agreement) provide comprehensive and standardize framework (i.e under Article 7) to harmonize cum minimize the residual gap for both north (well developed) and south (less developed) country's productivity and level of technological transfer.

Most empirical studies found that, economic growth (as a measure of productivity) is endogenously driven, inter alia through input factors (Solow,1956) and technology only assimilates through the process of capital accumulation and human capital creation exogenously to the model to indirectly measure productivity (Mankiw et.al.1992; Miller and Upadhyay, 2000). But nowadays the effect of technology to economic growth shared among nations at least by several channels inter-alia trading, licensing, and foreign investment. Maskus and Penubarti (1995), first uncover the (little) importance of patent protection framework to bilateral trading flow (especially imports) between developing nations as an increase of patent protection. Moreover, Smith (1999, 2001) found the sensitivity of unidirectional evidence of exports flow to difference function of patent protection level. Due to the growing trade pattern of high technological product, trade opportunities have benefited nations especially to at least accumulate technological know-how as an alternative channel to energize growth's speed up process.

Stringent protection, among developing and less-developing countries has at least delaying the innovation creativity initiated from developed countries. Eaton and Kortum (1996), found evidence that 50% of growths in the OECD countries are facilitated by an invention and innovations originated from developed countries such as United Stated, Germany and Japan. Japan has experiencing an upward trend in technical progress (post war growth) due to an effort and progress of enhancing patent framework (Maskus and McDaniel, 1999). Liu and Wang (2003) link the mechanism possibility between foreign direct investments (FDI) to total factor productivity (TFP). They believe that according to endogenous growth model theory, TFP is assumed to be synonymous to technological progress that assimilates through FDI flow. Markusen and Venables (1999) found

evidence of some linkage effects in local industry development where FDI has shown formally as an industrial catalyst.

A lack of transparency, less degree of openness, high country risk, black market activity, exchange rate distortion, high tariff rate and strong barrier and corruptions (widely blamed) have impediment power through various ways. Researchers, Gould and Gruber (1996), Smarzynska and Wei (2000), Wei and Wu (2001), Park and Lippoldt (2003), Gastanga et.al (1998), Paldam, M (2002) and MO, Pak Hung (2001) agreed that those factors are examples of self-created distortion instrument which silently retards the economic progress, especially in attracting foreign investors.

Good governance or institutions are measured by the efficiency of how one authority allocates resources efficiently from being exploited by legally private-interest agents. As purposed ideally by laissez faire system, allocations of factors are efficiently distributed through the pricing system mechanism. However, due a bureaucratic maze the effectiveness of economy delivery system in formalizing open macro economic policies becomes inefficient (Bai and Wei, 2000) especially in attracting foreign investment (Gelos and Wei, 2002). Other studies conducted by Hines (1995) and Wei (1997a, 1997b and 2000), conclude with the same finding[13].

THEORETICAL FRAMEWORK

From the previous empirical studies, the expected sign for each coefficient can now be formalized. Both coefficients for IP protection level and ratio of R&D expenditure to GNP are expected to be positively correlated to FDI. However, BMP variables negatively related to FDI.

To analyze the impact and magnitude of the said factors, this paper proceeds with the development of an econometrics model as describes below.

$$y_i = \alpha_0 + \alpha_i \chi_i' + u_i \qquad \text{(Eq.1)}$$

y_i = Inflow of FDI by foreign investors

χ_i = A sets of explanatory variables namely Patents protection index (IPRS), Black Market Index (BMI) and domestic R & D expenditure (RDEXP).

By following the properties of Classical Linear Regression Model assumption (CLRM), it is worth to noted here that the conditional expected value for the error term are zero and follows the homoscedasticity distribution as shown by the respective equation $E(u_i \mid \chi_i) = 0$ and $var(u_i \mid \chi_i) = \sigma^2$.

The coefficients for IPRS and RDEXP are hypothesizing positively related to FDI, however BMI inversely related to FDI inflow to the host countries. We also look into the possibility of dummy interaction within and between the explanatory variables. Since the data set is involving a cross country sample, therefore another dummy variable to capture country specific development level will be constructed using the newly release World Bank income classification (as of July 2003) to find out the effect of FDI investment accordingly to the income classification. The construction of dummy variable is explained in the subsection 4.2.1.

Since all data were obtained from various sources, countries involved in the sample set were different in historical records, intensity and development levels, therefore heteroscedasticity problem suspected to exist in the model. The heteroscedasticity problem moreover will invalidate (biased) the variance dispersion for each coefficient in the model and the usual reported statistics produced by the usual OLS procedures unfortunately no longer distribute accordingly to the CLRM assumption. In short, the statistics methodology used to test hypothesis under the Gauss-Markov assumption are less valid in the presence of heteroscedasticity[14]. This problem usually reported by many researchers when dealing with cross sectional and cross-country data. As an alleviate measure, we will perform White Heteroscedasticity-Consistent Standard Error and Covariance.

The existence of heteroscedasticity indicate that some sort of functional problem. Therefore regression specification error test (RESET) developed by Ramsey's (1969) will be conducted. Although the RESET test only can detect and identify such misspecification but the heteroscedasticity problem occurred in the model still not corrected. Therefore to deal with the problem, again White (1980) heteroscedasticity methodology test came

---

[13] However, Alesina and Weder (1999) did not found any empirical evidence when study about "Do Corrupt Governments receive less foreign aid".
[14] Wooldridge, J.M (2003)

into practice. We will also perform autocorrelation test to detect some space correlation of the residual in the model.

MODEL CALIBRATION AND HYPOTHESIS DEVELOPMENT

In this section we will discuss the empirical model suggested in the previous section. The suggested equation will be estimated for each cross-country denoted by subscript i. The model is as follow:

$$\ln FDI_i = \alpha_0 + \alpha_1 \ln IP_i + \alpha_2 \ln RND_i + \alpha_3 \ln BMI_i \qquad (Eq.1.1)$$

Each of the variables transformed into its logarithm form to allow for percentage impacts to the estimated coefficients. FDI_i[15] is the inflow of FDI in the reporting (host) economy comprises capital provided (either directly or through other related enterprises) by a foreign direct investor to an FDI enterprise resident in the economy. $IPRS_i$ is the unweighted patents protection strength framework, which was developed by Park, and Ginarte (1997) using standard patent book of law and BMI_i[16] is the black market index as a proxy to transparency level and efficiency of the domestic market. Both $IPRS_i$ and BMI_i are the example of designed institutional factors that governed by the government of each receiving countries. The black markets activities in reality are sometimes beyond the government's control, but with strong enforcement, regulation and continuous monitoring process it will reduce such activity.

The hypothesize sign derived in Eq.1.1 are as follows:
$$\alpha_1 > 0, \ \alpha_2 > 0, \ \alpha_3 < 0$$

To examine the interaction term and its effect to inflow of FDI, we developed eleven extended models to the equation Eq (1.1).

Construction of Dummy Variables

The process of regroup the explanatory variables into its dummy value are quite simple. We start the process by identifying the normality distribution of all variables. To test for normality distribution for each of explanatory variables, we apply the Anderson-Darling, A^2 procedure. The Anderson-Darling, A^2 statistics for all explanatory variables are presented in the summary statistics Table 5.1.

If all the variables normally distributed around its mean value, therefore we will use its mean value as a balanced-point measurement of distributions to regroup the variables. However if all the variables are found skewed or does not normally distributed around its mean, we will use median value as a center of distribution to regroup the variables.

Simple Effect Two-Way Dummy Interactions Model

For the interaction term between the dummy variables (i.e categorical variables) with other explanatory variables (i.e continuous variables), we developed twelve extended model for each dummy groups variables.

$$\ln FDI_i = \alpha_0 + \alpha_1 \ln RND_i + \alpha_2 \ln BMI_i + \alpha_d \sum_{d=0}^{1} Dip + \alpha_{di} \ln IP_i \sum_{d=0}^{1} Dip \qquad (Eq.1.2)$$

The above equation examines the effect of level of FDI inflow for each group given the level of IPRS and assuming other explanatory variables unchanged. The coefficient α_{di} denotes the effect level of FDI received by the countries.

$$\ln FDI_i = \alpha_0 + \alpha_1 \ln IP_i + \alpha_2 \ln BMI_i + \alpha_d \sum_{d=0}^{1} Dip + \alpha_{di} \ln RND_i \sum_{d=0}^{1} Dip \qquad (Eq.1.3)$$

$$\ln FDI_i = \alpha_0 + \alpha_1 \ln IP_i + \alpha_2 \ln RND_i + \alpha_d \sum_{d=0}^{1} Dip + \alpha_{di} \ln BMI_i \sum_{d=0}^{1} Dip \qquad (Eq.1.4)$$

---

[15] For explanation of FDI inflow used in this paper, refer to UNCTAD Handbook of statistics which are available online at http://stats.unctad.org/
[16] BMI value is actually adapted by the authors from survey conducted on the Transparency International's Corruption Perception Index which taking ordinal value 1 through 5.

The interactions of Dummy IPRS with other explanatory variables are represented by (Eq.1.2), (Eq.1.3) and (Eq.1.4).

$$\ln \text{FDI}_i = \alpha_0 + \alpha_1 \ln \text{RND}_i + \alpha_2 \ln \text{BMI} + \alpha_d \sum_{d=0}^{1} \text{Dbmi} + \alpha_{di} \ln \text{IP}_i \sum_{d=0}^{1} \text{Dbmi} \quad \text{(Eq.1.5)}$$

$$\ln \text{FDI}_i = \alpha_0 + \alpha_1 \ln \text{IP}_i + \alpha_2 \ln \text{BMI} + \alpha_d \sum_{d=0}^{1} \text{Dbmi} + \alpha_{di} \ln \text{RND}_i \sum_{d=0}^{1} \text{Dbmi} \quad \text{(Eq.1.6)}$$

$$\ln \text{FDI}_i = \alpha_0 + \alpha_1 \ln \text{IP}_i + \alpha_2 \ln \text{RND} + \alpha_d \sum_{d=0}^{1} \text{Dbmi} + \alpha_{di} \ln \text{BMI}_i \sum_{d=0}^{1} \text{Dbmi} \quad \text{(Eq.1.7)}$$

The interactions of dummy BMI with other explanatory variables are represented by (Eq.1.5) and (Eq.1.7).

$$\ln \text{FDI}_i = \alpha_0 + \alpha_1 \ln \text{RND}_i + \alpha_2 \ln \text{BMI} + \alpha_d \sum_{d=0}^{1} \text{Drnd} + \alpha_{di} \ln \text{IP}_i \sum_{d=0}^{1} \text{Drnd} \quad \text{(Eq.1.8)}$$

$$\ln \text{FDI}_i = \alpha_0 + \alpha_1 \ln \text{IP}_i + \alpha_2 \ln \text{BMI} + \alpha_d \sum_{d=0}^{1} \text{Drnd} + \alpha_{di} \ln \text{RND}_i \sum_{d=0}^{1} \text{Drnd} \quad \text{(Eq.1.9)}$$

$$\ln \text{FDI}_i = \alpha_0 + \alpha_1 \ln \text{IP}_i + \alpha_2 \ln \text{RND}_i + \alpha_d \sum_{d=0}^{1} \text{Drnd} + \alpha_{di} \ln \text{BMI} \sum_{d=0}^{1} \text{Drnd} \quad \text{(Eq.1.10)}$$

The interactions of dummy RDEXP with other explanatory variable are represented by (Eq.1.8), (Eq.1.9) and (Eq.1.10) above.

$$\ln \text{FDI}_i = \alpha_0 + \alpha_1 \ln \text{RND}_i + \alpha_2 \ln \text{BMI}_i + \alpha_d \sum_{d=0}^{1} \text{Dinc} + \alpha_{di} \ln \text{IP}_i \sum_{d=0}^{1} \text{Dinc} \quad \text{(Eq.1.11)}$$

$$\ln \text{FDI}_i = \alpha_0 + \alpha_1 \ln \text{IP}_i + \alpha_2 \ln \text{BMI}_i + \alpha_d \sum_{d=0}^{1} \text{Dinc} + \alpha_{di} \ln \text{RND}_i \sum_{d=0}^{1} \text{Dinc} \quad \text{(Eq.1.12)}$$

$$\ln \text{FDI}_i = \alpha_0 + \alpha_1 \ln \text{IP}_i + \alpha_2 \ln \text{RND}_i + \alpha_d \sum_{d=0}^{1} \text{Dinc} + \alpha_{di} \ln \text{BMI}_i \sum_{d=0}^{1} \text{Dinc} \quad \text{(Eq.1.13)}$$

The interactions of dummy income classification with other explanatory variables are represented by (Eq.1.11), (Eq.1.12) and (Eq.1.13).

To avoid fall into dummy variable traps, one group will be selected as a base or comparison group. Therefore for any effect to FDI, each group has its own unique intercept in explaining the level of FDI inflow.

Now the interaction of each dummy gives a simple effect and magnitude to the FDI, therefore the discussion will in fact discuss mainly into the issues of how these interactions affect and attracts the investment level into the certain group of countries, ceteris paribus. The signs of coefficients of α_{di} for each dummy interactions group can be either positive or negative. The positive (negative) sign denotes the simple effect level of FDI higher (lower) compared to other group of countries in each analysis.

The suggested model above were developed after taking into account of various factors (i.e issues covered in the literature review section) and hopefully to reach the conclusion of what were actually the impact of FDI inflow as an impact from the TRIPS agreement for different sets and specific characteristic of countries that largely depends on FDI in assessing full potential of economic growth (Park and Ginarte, 1997)

Model developed in (Eq.1.1) is principally a benchmark model. Sets of equations which started from (Eq.1.2) through (Eq.1.13) were developed and main concern is, as the model enhances and developed, the complexity of FDI impact will be revealed. The interaction term for each equation will give the explanations of why some countries received massive FDI compared to some other and what benchmark that investors look for when deciding to invest in certain counties given other factor unchanged as explained in (e.q.1.1).

ANALYSIS

The primary purpose of this paper is to examining the impact of inflow of FDI as an effect of increasing of patents right protection index (IPRS) as stipulated in the TRIPS agreement[17].

Table 3 and Table 4 represent the summary statistics (including the Anderson-Darling A^2 statistic) and correlation matrix for each of the variable used in the model. The variable used in the model exhibit heteroscedastic pattern especially involving FDI since data were obtained from cross-country sample and variations of variable are rather disperses. The preliminary examination about the nature of the data, motivate us to choose the appropriate model to examine the effect of FDI.

Table 3: Summary Statistics

	FDI	IPRS	RDEXP	BMI
Mean	17272.07	3.21	1.155	2.55

Note: (i) The usual OLS standard errors are in parentheses, ( ) and the heteroscedasticity-robust standard errors are in square brackets, [ ].
(ii) Value indicates with braces, { } is p-value.
(iii) Anderson-Darling A^2 is the normality test for predicted residual
(iv) The value of Wald coefficient test, White heteroscedasticity test and BG space correlation test are reported after the model corrected for the existence of heteroscedasticity.
(v) $^{*},^{**},^{***}$ Indicates the coefficients significant at 10%, 5% and 1% respectively.

For OLS (1) of Table 5, the usual standard error and robust standard error are reported in parenthesis and bracket, respectively. The coefficient for lnIP is statistically significant at least at 1 percent level for both robust and non-robust equations. As 1 percent increase in patent protection will increase the inflow of lnFDI to around 4 percent.

The OLS (2) equation conducted with including two additional explanatory variables and the robust and non-robust standard error reported in bracket and parenthesis respectively. The explanatory power of OLS (2) equation is around 48 percent. The sign of each variables parallel with earlier hypothesis. Two explanatory variables (i.e lnIP and lnRND) found significantly different from zero at least at 1 percent level and lnBMI is not. To test the significant of inclusion additional explanatory variables we apply Wald coefficient restriction test[18]. Wald test shows that both additional explanatory variables significant at least at 1 percent level and this is an indicator that the additional explanatory variables are belong to the model.[19]

---

[18] The Wald test computes the test statistic by estimating the unrestricted regression without imposing the coefficient restrictions specified by the null hypothesis. The Wald statistic measures how close the unrestricted estimates come to satisfying the restrictions under the null hypothesis. If the restrictions are in fact true, then the unrestricted estimates should come close to satisfying the restrictions.

[19] As stated earlier, if heteroscedasticity exist in the model, it will misinterpret the results. Therefore, to confirm, we conduct White (1980) heteroscedasticity LM test (with cross term interaction). The chi square (χ^2_6) test fails to reject the null hypothesis of homoscedasticity at least at 11 percent level. Therefore, we might say that the heteroscedasticty robust version is now alleviated from heteroscedasticity problem.

The problem of sample first-order autocorrelation is also tested. The autocorrelation problem usually exists in time series observation, but it might exist in space for cross sectional observations. In this paper we conduct methodology developed by J.Durbin and G.S Watson (1951). The D-W test is only valid when the error term is assumed to be normally distributed. Since the normality assumption is not violated in the model, we found that for all model there is no first-order autocorrelation at least at 1% level.

As we extend the model (OLS 3), by taking quadratic term for level of lnIP, it is found that, the explanatory power for this model increase slightly (around 50 percent) and the squared terms for lnIP significant at 5 percent (non-robust version) and 10 percent (for robust version) respectively. Thus this indicating those as the level of protection increase, level of FDI would also increase significantly after reaching some threshold level. Therefore we suspect the IPRs protections and its relations to FDI thus far are explained by a non-linear relationship[20].

Since the analysis using double log model it cannot identify accurately the optimum level of IPRs protections. Therefore we construct simple analysis with several interval values for each of explanatory variables[21]. Then we map the interval value accordingly to the country sample sets. The interaction in the analysis now gives unique features of countries characteristics and its relations to inflow of FDI into the receiving countries respectively. It is worth to emphasize that as the model developed, the complexity of FDI impact will be revealed. The interaction term for each equation will give the explanations of why some countries received massive FDI compared to other and what benchmark that investors look for when deciding to invest in certain counties given other factor remain unchanged.

THE SIMPLE EFFECT TWO-WAY INTERACTIONS ANALYSIS

The eleven extended regression equations as describe in section 4.2 (involving E.q.1.2 to E.q.2.2), will be examined and tested for the selected 56 sample sets. However for simplicity the results presented as in Table 5.4 only provide the analysis for partial interaction between variables. Since the interactions terms differ by way of interpretations and implications to the host's countries, the remaining analysis will develop into several subsections and discussed intensely into this matter. To examine the interaction between explanatory variables and its effect to FDI inflow, we developed four groups' dummy variables involving patents protection level (i.e. DIPRS), domestic market condition (i.e. DBMP), income classification based on newly release data from World Bank as July 2003 (i.e. DINC) and R&D intensity (i.e. DRND).

Interaction on dummy IPRs (Dip)

The results of simple effect for each of interactions with construct dummy variables are mixed for all set of extended regression version. For level of IP strength for group [0], only countries below the median value grouped benefited from such interactions. However, group for [1] no significant interaction was found although the interaction sign fit with the theory. 27 countries were identified from group [0] benefited from such protections (i.e. significant at 10 percent level).

The R & D activity becomes significant as the level of IP protection increase. As depicted in table 6, level of R&D intensity started benefited from the return of investment when IP strength equal or above 3.24. Group [1] R&D concentration significantly contributes to FDI inflow at 5% level. For group [0], although the effect is positive but it was found insignificant. The significant relationship between protection levels to R&D activity has the similarity to the results found by Varsakelis (2001).

The simple effect interaction for group [0] irrespective for market transparency level is positive (i.e shows the reverse sign from the stipulated theory). Nothing much we could say on this situation, but as we reexamine the data set, we found that most of the countries in the IP group [0] were developing countries with lower level of market transparency. The impact to FDI inflow is negative for IP group [1] and significant at 10 % level.

Interaction on dummy R&D (Drnd)

For most of the cases, the interactions of Drnd variables enhance the analysis in terms sign and magnitude impact of FDI. Given the group of R&D activity, an increase in R&D at any level of IP strength effects of FDI investment also increases significantly for both R&D group [0] and [1]. However the significant simple effect interaction is highly recorded for group [0] at 1 % level compared to 10% level for group [1].

The level of R&D intensity for both groups is positive, but the significant effect from the sample set only significant for below median level of the low level of R&D activity group (i.e group [0]). For high level group [1] though it is found positive but the positive impacts were found insignificant.

---

[20] This finding reveal that for the 56 sample involved in the analysis, the patterns of patent protections is some what follows the "U" shape analysis. However since the model consist of various countries and the equations developed are in double log analysis, we are unsure about the break point level of the IPRs. One possible measure to detect such break point is to divide the level of IPRs of those countries into its unique classifications.

[21] Including Dummy for income classifications as represented by E.q.2.0 to E.q.2.2

However the simple effect interaction for both Drnd group irrespective of market transparency level is found insignificant though the interaction sign meet the earlier expectations. The insignificant results between interaction terms coefficient are due to the specific characteristics of each group across country and observation in the sample set.

Interaction on dummy BMP (Dbmi)

For interaction between groups dummy BMP and other two explanatory variables, it seems that irrespective of level IP strength and R&D intensity, both group shows a positive and significant simple effect two way relationships.

For group [0] the positive relationship with IP strength is significant at 5% level and 1% level for group [1]. By given the level of IP strength, the negative impact of market transparency for any country falls under each group has been whip out by the stronger positive impact of IP level. This statement supported by the strong positive simple effect interaction for group [1]. Therefore the level of BMP in any certain country does not affect investment in FDI.

The interaction results between group dummies BMP irrespective of R&D level also shows a positive relationship. However the significant effect only recorded for group [1] and not for group [0]. Therefore once again, for group [1] BMP, market transparency distortions has fail to reverse the impact of foreign investment inflow by intensifying R&D activity at least for this selected sample set.

Interaction on dummy Countries Development (DLevel)

Level of income is an indicator for nation's development level and an increase in income, enhances the nation's standard of living and so the awareness of protecting the intellectual property rights are in optimal level. Therefore, to scrutinize the country specific development level, we use the latest World Bank income classification (as of July 2003) to examine the impact of countries inflow of FDI. The dummies for country's income are divided into five main groups' viz. high income-OECD, high income- Non-OECD, Upper middle income, Lower middle income and low-income countries. The interactions between countries development level with sets of explanatory variables viewed as an important perspective since it can reap better understanding about the nature of foreign investment flow.

For the purpose of this study, we regroup the income classifications into two groups. Namely group [1] for a developed country consists of high-income OECD countries and high-income Non-OECD countries and group [0] for developing countries consists of three income classifications i.e upper middle income, lower middle income and low-income countries.

For developed countries, all three simple effect interactions found significant in international investment inflow. The IP strength framework is significant at 1 %, R&D intensity significant at 5% level and market transparency only significant at 10% level. However for developing countries, we did not found enough evidence that market transparency distortion will affect the investment inflow. Strong evidence however found from the IP strength framework and R&D intensity activity where both significant at 1% and 5% respectively.

Table 6: The Simple Effect Two-way Interaction of Protection Level, Market transparency, Income Classification and R&D Intensity to FDI inflow

		lnIP	lnRND	lnBMI
$\sum\limits_{d=0}^{1} Dip$	[0]	1.7795 {0.090}*	0.4438 {0.135}	0.3814 {0.732}
	[1]	4.2361 {0.160}	0.6789 {0.040}**	-0.7643 {0.094}*
$\sum\limits_{d=0}^{1} Drnd$	[0]	2.2924 {0.002}***	0.5419 {0.035}**	-0.2421 {0.802}
	[1]	3.7283 {0.099}*	0.0334 {0.966}	-0.3791 {0.573}

Notes:

For dummy variable classifications;
[0]- observations below its median value
[1]- observations above or equal to its median value

Dip is dummy variable for level of protection
    [0]: 27 countries
    [1]: 29 countries

Drnd is dummy variable for R&D per GNP
    [0]: 34 countries
    [1]: 22 countries

Dbmi is dummy variable for domestic market transparency
    [0]: 28 countries
    [1]: 28 countries

Dlevel is dummy level of development based on Country Income Classification by World Bank
(as July 2003)
    [0]: 30 countries
    [1]: 26 countries

The sign with *,** and *** are the significant level at 10, 5, and 1 percent respectively.

CONCLUSION

The issues of uniform IP protection are ambiguous and contentious. Though it is common for the developed countries to protect their intellectual property through various IP law channels, but the extent to which protection can be expanded to the developing nations remain challenging.

The mode or choice of entry for investment (from the empirical analysis) for those countries is indeed unique. Some countries provide strong IP protection to just comply with the ceiling standard, which is put in order by the international treaty. Fully comply with the standard will provide them with better foundation and stronger benchmark as to promote economic development activity within highly protected business environment and strong science and technological activity. These become the explanations for the location advantage. Investors however need secure environment package as their best options or *modus operandi* to secure their investment portfolio. Highly protected market (stronger IPRs) provided by host's countries had been proved as a favorable strategies (Gould and Gruben, 1996) however IPRs itself is not the ultimate factors for a success attractions of FDI (Park and Lippoldt, 2003). This however becomes a superior strategy for investors to identify newly potential market and provide an opportunity for mutually benefited innovative activity between nations.

Over the several decades inflow of FDI into the developing nations by means of R&D activity however, not only reflected by a stronger patent protections. The gaming situation for developing countries during the compliance periods of TRIPS agreement is proved by the success achievement from the developed (OECD and Non-OECD) nations. For the periods of 1996-2000, evidently shows that developed countries have benefited from such protections as one of an instrument and strategy to attract FDI.

Lall (2003) provide the dynamic perspectives and strategic dimensions for the developing nations in competing for strengthening IP protections using concept of different country measurement varied from domestic innovation intensity and foreign imports. He found that developing countries in complying with the standard ceiling requirements imposed by the TRIPS agreement however confronting with larger variation for uniformly developed strong IP across countries and concluded his paper with the statement;

"*In sum, two directions of policy emerge for developing country government: to exploit more fully and strategically the flexibility inherent in current TRIPS rules, and to analyse the TRIPS rules at a more fundamental level, with view to negotiating for a non-level playing field according to development needs".(Lall:2003, Pp. 1680)*

Therefore the decisions are now left to developing nations to freely decide the appropriate strategy to attract FDI to promote better economic foundation. For these countries, the *joint strategies* for attracting FDI were still remaining in questions.

In this paper we conclude with three potential options;
(1) *Move towards to provide more efficient IP protections,*
(2) *Intensifying technological research and development program;* and
(3) *Working towards combating illegal activity.* For this last option, developing countries were still behind due to insufficiency of intellectual property law enforcements.

The arguments of the abovementioned strategy are based on several reasons. (1) *Short term cost of offering efficient intellectual property protections* (2) *the benefits gained by the nations induced by an intensity of research and development* and (3) *to promote highly efficient market and safeguard to an increase in technological research activity*.

The Globalization ff Financial Markets:
Causes and Consequences to the Financial System

Tee Chwee Ming
Universiti Tuanku Abdul Rahman
13, Jalan 13/6
46200 Petaling Jaya, Selangor, Malaysia

ABSTRACT

Globalization remains an emotive issue that continues to be debated by government leaders, capitalist, business organization, social activists and religious figures. This research paper will only focus on the financial perspective and its link with the financial system. The first section presented various phases of financial globalization since 1870s. The second section looks at financial globalization from two dimensions; namely the blessed and unblessed trinity and the pre-requisites of financial globalization. The final section comprises of two central themes namely; the catalyst that drives financial globalization and its consequences to the domestic and international financial system. The benefits of financial globalization depend on how well the country's political and financial institutions integrate with the international financial system.

INTRODUCTION

Financial globalization is broadly defined as the integration of countries into international financial markets, which entailed the expansion of financial dealing and trading beyond domestic financial markets. The globalization of financial market is expected to lead to the progressive decline of restrictions on the movement of capital across political boundaries and deregulation of financial markets. Nevertheless, financial globalization is not a new phenomenon as its roots can be traced back to the last quarter of the 20th Century. The evolutionary process of financial globalization can be divided into 4 major phases, each with different features.

Gold Standard (1870s-1913)

This era coincide with the period of colonialism of Western powers led by Great Britain. Cross border capital flows surged, incorporating colonial powers in the center, which was supported by its colonies as periphery in a worldwide network of finance and investment. Raw materials were extracted from periphery countries and shipped back to colonial powers to generate capitalist profits. The capitalist profits from center were reinvested in periphery countries. As such, capital flows from center to periphery without any restriction.[i] This period of unregulated financial globalization from 1870s to 1913, according to Eichengreen and Bordo (2002), was marred by a series of banking crises due to speculation, excessive lending, imprudent banking regulation and supervision, institutional weaknesses, non-transparency and non-disclosure of information. Nevertheless, banking crises tend to be country specific.

Protectionism (1914-1945)

Two World Wars from 1914-1918 and 1939-1945 and the Great Depression from 1929-1932 put an abrupt end to international capital movement due to massive loss in output growth and capital from 1919 to 1939 (Arestis & Basu 2002, p.1).[ii]

Bretton-Woods (1945-1971)

A slow reconstruction of the international financial system and structure took place post 1945. Heavily regulated financial markets, fixed exchange rate and capital control, dominated this period. Banking crisis was eliminated by these series of measures but not currency crisis according to Arestis and Basu (2002). Financial globalization has to take a back seat as the world redress pressing issues like economic growth and employment after two devastating World Wars.

Post Bretton Woods (1973-Present)

The process of liberalizing financial markets around the world gained momentum again after the dismantling of the Bretton-Woods fixed exchange rate regime in 1973, which had created stability in the international financial market, albeit minimum financial integration. However, floating exchange rate creates volatility in the foreign exchange market and interest rate.

The last 25 years of the 20th century saw a new wave of international financial integration with the dismantling of capital controls, deregulation of domestic and financial innovation.[iii] Such a new wave of financial exuberance, which was last seen during the period of 1870s-1913, was supported by technology innovation, rapid dissemination of information and telecommunication.

However, the downside of free movement of capital is the re-emergence of banking crisis on top of the currency crisis. The impact of crisis tends to be on a global scale. Kaminsky and Reinhart (1999) use the term of twin crises to describe this new phenomenon.

GLOBALIZATION PERSPECTIVES

The analysis of financial globalization can be generally viewed from two perspectives; namely beneficiary and requirements of financial globalization.

Firstly, the analysis of financial globalization beneficiary has to take into consideration the relations between the role of money as store value, asset price stability and contractual and regulatory institutions. Torre, Yeyati and Schumukler (2002) study links these above elements with the concept of blessed and unblessed trinity.[iv] Blessed trinity component consists of international currency, flexible exchange rate and sound contractual and regulatory environment, while unblessed trinity is defined as weak currency, fear of floating exchange rate and weak institutional framework. [v] The study concluded that a country's financial system is likely to receive net benefit from financial globalization if it falls under the blessed trinity category. Likewise, premature liberalization of the financial sector tended to result in contagious financial crisis, like in the case of East Asian Currency Crisis 1997-1998 (IMF 2004, p.151-152).

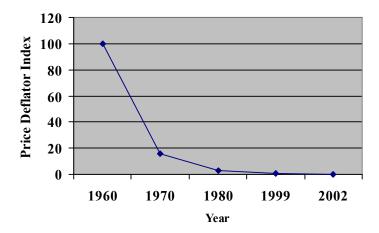
The first element of blessed trinity is international currency. When domestic currency is also a credible reserve currency abroad to store value, the government and residents of a trinity-endowed country can issue debt denominated in domestic currency without having to incur foreign exchange risk. However, in an unblessed trinity environment domestic investors are reluctant to hold domestic denominated assets.[vi] As such, domestic financial institutions have to borrow in foreign currency and incur the risk of maturity and currency mismatch on its balance sheet.

Secondly, flexible exchange rate enables a country to adjust its real exchange rate to solve the problem of excess capacity and unemployment. However, fixed exchange rate distorts the allocation of financial resource through mis-pricing of risk, as shown in the study of McKinnon and Pill (1997). This will serve only to increase the country's vulnerability to speculative attack as Dooley (2000) strongly argued.

Finally, the status of international currency and benefits of flexible exchange rate to the financial system has to be preceded by sound contractual and regulatory institutions. Central bank's policy on asset price stability and prudent regulations has to be seen as credible and independent from political interference, which is unfortunately prevalent in countries that fall under the unblessed trinity category.

The second type of analysis is the prerequisites of financial globalization. Arestis and Basu (2002) argue that for a truly integrated financial system; two main prerequisites have to be achieved. They are alignment of interest rate and a world currency union. The former is unachievable as different countries have different risk premium due to its structural economic dissimilarities. The latter can only be achieved if the wealth gap between rich and poorer countries is narrowed.[vii]

CATALYST OF FINANCIAL GLOBALIZATION

Technology Innovation


The increasing speed of capital mobility between different financial markets is largely attributed to the technology advancement in the field of electronic telecommunication and communication.[viii] Information can be acquired, processed, analyzed and disseminated rapidly and broadly to facilitate faster trading and decision-

making. As such, cross arbitrage opportunities between different financial markets have increased. Time zones differences and long distance is no longer a crucial barrier for investors, speculators and arbitrageurs in search of the best yield in different financial markets.

Cost is another prerequisite of financial globalization. In the past forty years, technology advancement correlates negatively with cost of procuring the necessary hardware equipment and software program as shown in Figure 1. Cost is a major factor of financial integration of multiple financial markets.

Thirdly, computing speed and cost factor is complemented by mass usage of the masses. The spread of internet technology to the masses has resulted in the proliferation of online stock and foreign currency exchange brokerages, especially in the US, which allows professional traders and the public to trade in stocks and currencies denominated in different foreign currencies and financial markets.

Figure 1: US Computer Price Deflator, 1960 - 1999

Source: US Department of Commerce, 2002

Elimination Of Capital Control

The Bretton-Woods fixed exchange regime views freedom of capital movement beyond national sovereign border, which is not due to foreign direct investment and trade as undesirable and should be discouraged (Yilmaz 1992, p.46). This can be achieved by imposing capital control to curb speculative activities, which is detrimental to the financial stability and long-term economic growth of the country. Table 1 shows the pre and post impact of the East Asian Currency Crisis in 1997-1998 on GDP growth.

Table 1: East Asian Economies GDP (%), 1995-1999

Country	1995	1996	1997	1998	1999
Indonesia	8.22	7.82	4.70	-13.2	0.23
South Korea	8.92	6.75	5.01	-6.69	10.66
Malaysia	9.83	10.00	7.54	-7.50	5.42
Philippines	4.67	5.85	5.19	-0.59	3.32
Thailand	8.90	5.93	-1.68	-10.17	4.16

Source : Asian Development Bank, 2000

The progressive disintegration of the Bretton-Woods fixed exchange rate regime accelerated in the early 70s and culminated with the decision of President Richard Nixon to de-link US dollar from gold in 1973 (Walter & Blake 1992, p.79 & Gilpin 1987, p.140). The US decision spelt the beginning of the end of the capital control era, as more countries moved to float their currencies.

Disincentive To Maintain Capital Control

Firstly, policies that establish barriers between national and global financial markets only serve to push such markets offshore. For example, in the 1990s, traders circumvented Japanese Ministry of Finance attempt to

prohibit the trading of Nikkei index derivatives by establishing an offshore center at Singapore (Garret 2000, p.17). Malaysia has its own share of problem when CLOB market was operational out of the Malaysian securities regulator's jurisdiction until 1998. [ix] Re-regulation at global level is only possible, provided the problem of free rider can be avoided since it only takes one jurisdiction to offer a home to offshore financial markets. Once government discovers the ineffectiveness of capital control, they tend not to retain it.

Secondly, contemporary financial globalization is distinctively different from the pre-1914 world. Then, the high cost of delivery and delays in communication and information and the underdevelopment of financial and derivatives market meant that even the unsophisticated capital control could work. [x]

However, experience in Chile, China, Malaysia and India seem to suggest that capital control could still work in today's volatile financial market. Krugman (1999), Stiglitz (2000), Kaplan and Rodrik (2001) defend the effectiveness of capital control in the event of extreme volatility and financial distress. Though, it work well, all believe capital control should be a temporary measure.

FINANCIAL MARKET DEREGULATION

The theoretical rational of financial deregulation is to eliminate financial pricing distortion, which results in misallocation of resources. This leads to cost efficiency of delivering financial product and pricing. The framework to achieve the above objectives can be argued from two perspectives.

Structural Deregulation

Firstly, once financial deregulation has been effected, there can be no discrimination between foreign and local chartered banks.[xi] Foreign banks are now allowed to venture into domestic loan business, where they were previously prohibited.

Another dimension of structural deregulation can be viewed from the operations integration perspective. Before deregulation, financial institutions are confined to very narrow definition of permissible business operations. In the case of UK's financial deregulation, known as the *financial big bang* in 1986, one of the major features is the ending of business segregation between traditional banking and securities. The relevant laws were amended in 1986 to allow for the purchase of securities/brokerage by banks, *vice versa*. Banks can now engage in traditional retail/commercial banking and securities business at the same time, thus ending the 300 years segregation and separation of banking and securities business in UK financial system. Japan embraced desegregation in 1993 through the Financial System Reform Law and European Union member nations in 1996 (Dale 1996,p.220-221). In the US, the separation of banking and securities business holds by the virtue of the Glass-Stegall Act of 1933 but the separation was finally repealed in 1999 through the Gramm-Leach-Bliley Act (Zaretsky, A 2000,p.1).

Deregulation initiatives led to the attainment of economics of scale and even possible economics of scope through the creation of business synergies. The average fixed cost of delivering financial products would have substantially been reduced as total fixed cost would spread across banking and securities business. Thus, lower cost of doing business and efficiency has provided a considerable impetus to the proliferation of financial conglomerates, which are willing to venture beyond their domestic market of operations.

Financial Instrument Liberalization

Interest rate liberalization is a first step towards promoting efficiency in loan pricing and origination. However, banking industry structure is oligopolistic. As such, the number of players in the banking sector ought to be increased. This can be achieved through the removal of entry restriction for Non Banking Financial Institution (NBFI) and foreign banks.

In Malaysia, NBFI is non-existent despite the fact that it has company like Petronas in the Top 500 Fortune list. With its huge case reserve from oil and gas proceeds, Petronas possess the financial muscle to offer financial services to the capital market. Hence, it is time for Bank Negara Malaysia to promote the role of NBFI through deregulation with the aim of achieving financing deepening and competitive financial product pricing.

Nevertheless, deregulation and capital control account liberalization has to be complemented by a good financial system. A good financial system should consist of the following eight key components: -
- Prudence in public finance and debt management.

- Stable monetary policy.
- An autonomous central bank capable of managing domestic and international finance. Implemented monetary policy should promote robust, sustainable and quality economic growth.
- A well functioning capital markets.
- A competitive financial services industry that comprise of domestic and international chartered financial intermediary.
- Independent and credible judiciary and law enforcement agencies. This will minimize the principal-agent problem that is inherent to financial systems. Contract enforcement, underpinned by transparent shareholder and creditors rights and a trustworthy judiciary shall be able to reduce information asymmetries.
- Sound regulatory environment ensures proper risk management practices. This can be derived through good accounting and information standards of disclosure, risk based capital requirements and prudential supervision of financial services sector in accordance to international accepted standards.
- Competent, corrupt free and credible government in the eyes of international investors.

CONSEQUENCES OF FINANCIAL GLOBALIZATION

Financial Crisis

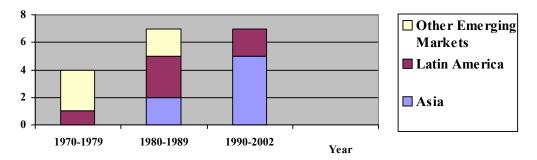
The 1990s were marked by a series of major financial crisis worlwide.[xii] Although financial crisis is not new, a study conducted by Bordo, Eichengreen, Kiligebiel and Martinez-Peria (2001) concluded that a crisis during contemporary period of financial globalization is more frequent than earlier periods. Eichengreen and Bordo (2002) provide evidence that the probability of a country suffering from a financial crisis doubled post Bretton-Wood 1973. Developing countries seem to bear the brunt of the crisis as opposed to a developed nation. This could be due to the fact that developing nations borrow in developed nation denominated currencies like US dollar, Pound Sterling and Yen. The Asian currency crisis in 1997 was due to the accumulated foreign debt of short-term maturities and the failure of developing countries to hedge against currency exchange risk. By contrast, financial globalization has created an option for developed countries to borrow from international investors in their own domestic currency denominated assets. However, unlike the former, developed nations are not subjected to currency exchange rate risk.

Nevertheless, the impact and duration of financial crisis is less profound than in the past. This could be largely due to prudential regulation, regional co-operation and sound surveillance on the financial system. A good example is the Basle Capital Accord I, which was first introduced in 1988. It established an 8% minimum (weighted) capital adequacy for international banks. Basle Capital Accord II which is scheduled to be implemented starting from 2006 sought to redress the issue of using asset securitization and derivatives instruments to minimize capital charge without modifying the underlying risk. Basle II aims to widen its global coverage due to the globalization of financial markets. Thus, when markets are global so must the regulation as economic and financial stability according to Wyplosz (1999) takes on the character of a global public good. The quest to internalize externalities would require domestic policy and regulation to be realigned to international standards.

Rising financial linkages gives rise to potential contagion effects. Investors, speculators and arbitrageurs' quest for higher returns and portfolio diversification has been supported by the decline in information and transaction costs and access to investment opportunities on a global scale. Nevertheless, while opportunities to make capitalist profit have increased, one should not ignore the emergence of two broad types of contagion, namely fundamental based contagion and pure contagion. The former refers to transmission of financial shocks across national borders due to the weakness of a country's economy. Decision by investors to reassess their investment risk could develop into a domestic financial crisis if the economic fundamentals are weak. The domestic financial crisis can evolve into a regional crisis as bankers start to rebalance its lending portfolio by restricting lending to the affected region.[xiii] This will only accentuate the crisis in emerging markets as large fraction of bank lending is in the form of short-term maturity according to the findings of Van Rijckeghem and Weder (1999). Kaminsky and Reihnart (1999) found out that fundamental based contagion could reach the proportion of an international scale, as demonstrated by the Russian sovereign bond default crisis in 1998. However, one important observation can be made on the financial crisis that transpired during the period of 1997-1998. Although the impact of crisis has taken on a global scale, countries with stronger economic fundamentals were able to withstand the transmission of financial shocks better. [xiv]

Secondly, pure contagion effect is not attributed to structural or fundamentals of the economy. The sharp swing in the international capital flows tends to be speculative and short term in nature. This leads us to the concept of herding, where there is a tendency for investors to follow the crowd, at the expense of fundamental analysis and

information. Fund managers tend to align their portfolio to the performance of the benchmark indices by implementing the strategy of momentum trading. [xv] The advent of technology and communication increases the magnitude of the destabilizing effect on financial markets, which will be transmitted into the economy. Momentum trading thrives on information asymmetries. Information asymmetries is due to risk that cannot be totally eliminated like terrorism, political conflicts, epidemic which cost big economic losses in the case of SARS and non regular events like spikes in oil prices and financial fraud like in the case of BCCI in 1991 and Barings Bank in 1995. Nevertheless, Gelos and Wei (2001) finding shows that the impact is less severe in countries with sound macroeconomic fundamentals and transparent corporate sectors.

Both types of contagion create systemic risk to the financial system. The risk can be categorized into either a sequential or simultaneous pattern. The former consists of a situation where the failure of a financial institution led to another financial institution failure in a sequential manner, while the latter leads to a simultaneous failure of a group of banks, which have potential to destabilize the financial system. In the integrated payment and settlement system, the balance sheet of financial institutions is directly inter-connected to each other because they borrow and deposit funds among themselves. As financial transactions are globalized, risk in foreign exchange settlement arises because the settlement encompasses two legs of foreign exchange transaction that typically takes place in a situation of multiple payment systems, geographical locations and time zones. This interconnection provides an avenue, where financial shocks can be transmitted to every financial institution within the system, in an event of a financial failure. With the globalization of financial markets, financial shocks are no longer confined to domestic market but are extended to international markets. The more financial markets are integrated, the higher is the severity of the impact of systemic risk on the financial system.


Finally, financial crisis are incompatible with output growth. Bordo et al (2001) are of the opinion that output costs ranged from 6% for individual currency and banking crisis to 19% for crisis having banking and currency components. Normally a currency crisis is preceded by a banking sector problem, like in the East Asian currency crisis. This is a major finding by Kaminsky and Reinhart (1999), whereby the currency crisis serves only to augment the banking crisis, thus, activating a vicious cycle of financial crisis. Banking and currency crisis is closely associated with credit boom, which will be discussed in the following section.

Credit Boom

Banking and currency crisis are often precipitated by credit boom. IMF (2003) survey concludes that about 75% of the credit booms in emerging market economies were associated with banking crisis while as for currency crisis the figure is 85%. The survey underlines three catalysts of credit booms, namely, financing deepening, normal cyclical upturns and excessive cyclical movements or credit boom. The last catalyst creates an excessive and unsustainable credit expansion, which will eventually collapse on its own accord.

Credit booms are synchronized across countries. About 40% of the credit booms were observed in East Asia while 35% in Latin America as shown in Figure 2. Most of the East Asian credit booms took place in the mid 90s, which is a prelude to the Asian Currency Crisis in 1997. As for the Latin America credit boom, most were concentrated during the time of sovereign debt crisis in the early 80s (IMF, 2003 p.151-152).

Figure 2: Emerging Market Credit Booms, 1970 – 2002 (Number of Events)

Source: IMF, International Financial Statistics, 2003

The synchronization of credit booms across countries from 1970-2002 could largely be attributed to the capital inflow and financial liberalization. This can be observed from table 2. More than half of the credit booms were due to capital inflow, while only one sixth were attributed to financial liberalization within the period of 1970-2002.

Table 2: Credit Booms, Capital Inflows, and Financial Liberalization, 1970-2002

	Capital Inflows (%)	Financial Liberalization (%)	Capital Inflows and Financial Liberalization (%)
1970-2002	55.6	16.7	11.1
1970-1979	11.1	5.6	-
1980-1989	16.7	11.1	5.6
1990-2002	27.8	-	5.6

Source : Abiad & Moody (2003)

The mechanism to create credit boom can be explained from the financial accelerator perspective, whereby, shocks to asset prices are amplified through balance sheet effects due to financial market imperfections. The reasons for market imperfections are listed below.

Information asymmetries according to Kindleberger (2000) leads to herding behaviour by banks in terms of extending or withdrawing credit during good and bad times. In a bullish stock market environment, over-optimism about future earnings can boost the asset valuation of the company. [xvi] As a result, company can increase its corporate leverage by using its shares as collateral. However, this is not a sustainable practice as in the event of a financial meltdown asset prices and collateral value will decline. This can set off a vicious cycle when banks start to withdraw credit facility. [xvii]

Institutional weakness refers to imprudent macroeconomic policy and poor regulatory supervision standard, which creates moral hazard to the financial system. Failure to cool an over-heating economy in East Asia, which was supported through over-valued artificial exchange rate and capital inflow is a prime reason that leads to the Asian currency crisis from 1997 to 1998. As most central banks are not autonomous in most East Asian countries it is difficult to make monetary decisions that will make the government unpopular.

Adverse incentives and adverse selection are created, according to Corsetti, Pasenti and Roubini (1999) study, in an environment of explicit or implicit government guarantees. This will only exacerbate the principal-agency problem. In Malaysia, the government through the Bank Negara Malaysia gives explicit guarantee on deposit held by customers in financial institutions. For the customer, it is a risk free investment. Unfortunately, this blanket policy of bank deposit guarantees creates adverse incentives for banks to lend to risky borrowers for higher rates of return, knowing that they can always count on the government to bail them out with tax- payers money if it faces insolvency [xviii]

MONETARY AND FISCAL POLICY AUTONOMY

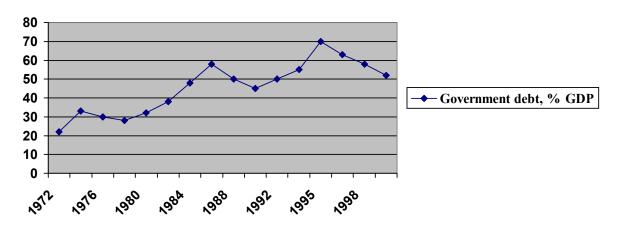
The Asian Currency crisis in 1997 was a stark reminder of the loss of autonomy when it comes to economic management of a country. [xix] Before the imposition of capital control in 1998 by the Malaysian government, there was Euro-Ringgit currency deposit offered by British banks in London. [xx] Prior to 1997 crisis, the interest rate on Euro-Ringgit deposit in London was in the region of 7%. Between 1997-1998, short-term currency speculation led to spikes in interest rate on Euro-Ringgit deposit. Suddenly, British banks were willing to pay as high as 30% on Ringgit deposit due to demand for the Malaysian Ringgit by currency speculators (Singapore Business Times 1st October 2001, p.5). When that happened, Bank Negara Malaysia was forced to raise interest rate on domestic deposits to prevent capital outflow from Malaysia. This proved to be ineffective and counter-productive to stem outflow of Malaysian Ringgit, as it only led to tit for tat interest rate hikes between off-shore banks and domestic banks. Currency speculators might see this as a matter of placing bets, risks and portfolio allocation but the impact on the Malaysian economy is debilitating to macroeconomic health and stability of the country in the long run.

Exchange rate has a direct implication on the level of autonomy enjoyed by the central bank on monetary policy. Floating exchange rate confers more autonomy to central bank on monetary issues as opposed to fixed exchange rate. The former allows central bank to align its monetary policy with domestic economic environment to pursue price stability. Thus, the flexibility of floating a currency allows the central bank to smooth out cyclical output and employment fluctuations to the extent that monetary policy has transitory real effects.[xxi] In the case of the

latter, the success of a fixed exchange rate regime requires the central bank to hold large reserves of international currency to lend credibility to the peg. Hence, the country's monetary policy is anchored to the monetary policy of a credible reserve currency. In the case of Hong Kong currency board system, there is limited monetary autonomy, as the decision making of the Hong Kong Monetary Authority is largely dictated by the US Federal Reserve. As such, in terms of retaining autonomy on monetary policy in a period of financial globalization, it is better to float the currency rather than maintain a fixed exchange rate regime.

As for fiscal policy, the globalization impact has been mixed at best. Empirical Studies by Garret (1998&2000), Kitschelt, Lange, Marks and Stephens (1999) found no evidence of clear direction towards less government fiscal intervention. Based on World Bank data on low and middle- income developing countries in Figure 3, there is a general increasing trend of government expenditure from early 1960s to 1980s before falling in the mid 1980s. Expenditure ratio to GDP increased again from mid 80s before it started to fall again in the early 1990s. Could financial globalization imposed constraint on government expenditure in the last two periods? However, Figure 4 seems to present an opposite trend. Since 1972, government debt is on an upward trend from a low of about 22% of GDP to a high of 70% of GDP.

Figure 3 : Low and Middle Income Developing Countries Government Expenditure, 1960-2000

Source: World Bank, World Development Indicators, 2001


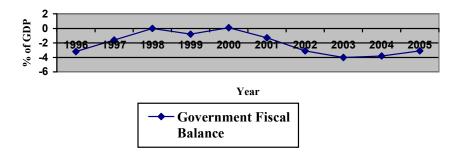


Figure 4 : Low and Middle Income Developing Countries Government Debt, 1972-2000

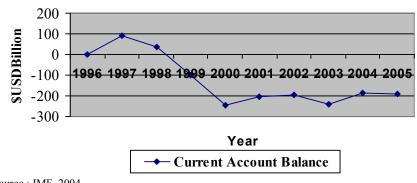
Source : World Bank, World Development Indicators, 2001


Figure 5 and 6 suggest that financial globalization does not seem to be able to impose fiscal discipline on advanced economies. The current account and fiscal balance have been deteriorating since 1996. The fiscal performance between advanced and emerging economies is illustrated in Figure 6 and 7. Since 1999, the increase in deficit of current account balance in advanced economies correlates with the increase in surplus in developing countries. While financial integration is supposed to promote prudent management of the economy, there seems to be two set of rules for advanced and emerging and developing countries. If developing and emerging markets were to record the performance showed in Figure 6 and 7, they would have been severely punished by the financial markets. This inconsistency could be due to the fact that advanced economies have all the three blessed trinities, whereby developing countries were impoverished by the three unblessed trinities.

DEVELOPMENT OF DOMESTIC FINANCIAL MARKET

The participation of foreign banks stimulates the growth of the domestic financial market. Firstly, foreign banks provide access to international financial markets due to its vast networking, reputation and experience. This

allows domestic financial institutions to diversify their operational, market and credit risk. For example, balance sheet risk held by domestic financial institutions can be lowered through syndication of a portion of corporate loan and underwriting business to foreign financial institutions. Secondly, liquidity of the domestic financial market is enhanced due to foreign capital inflows. This lowers risk premium borrowing rate for domestic banks, government and private sector. Thirdly, foreign financial institutions bring with them best management practices and regulatory and supervision framework into the domestic banking industry.[xxii] Finally, financial deepening is achieved in the domestic financial market through the introduction of financial and technology innovation by foreign banks. As such, studies by Levine (1996) and Caprio & Honohan (1999) show the entry of foreign banks tend to increase the level of competitiveness and quality of domestic financial services. These identified factors are categorized under pull factors.

CONCLUSION

The process of financial globalization is progressing at a breathtaking pace since 1990. There has been a massive increase in foreign exchange and portfolio capital flows in recent years. For the example, the triennial Bank for International Settlements (BIS) survey
showed that in April 2001, average daily turnover in spot foreign exchange markets
was $1.2 trillion, and average turnover in derivative markets was $1.4 trillion (BIS 2001,p1&9).

However, this research paper concludes that benefits due to financial globalization are disproportionately enjoyed by developed nations. This is because developed nations possess the three blessed trinity, which enable them to integrate well into the international financial system. Unfortunately, majority of the developing nations' financial system falls under the unblessed trinity. Hence, premature liberalization of their financial markets results in developing nations having to bear the pitfalls of financial globalization in the long run. Hence, it creates a widening wealth gap between rich and developing nation. If steps are not taken to redress this imbalance and unfairness in the trading of financial services, the process of financial globalization will only lead to even more uneven distribution of wealth between developed and developing nations. As history has demonstrated succinctly, economic deprivation could exacerbate social divide and political discontentment, which in turn could be transformed into a source of political instability to the world.

Endnotes: -

[i] Hirst and Thompson (1996) estimate that Britain was exporting an annual net savings of up to 9% of its GDP pre-1914.
[ii] Great Depression 1929-1932 was precipitated by US stock market collapse in the late 1920s.
[iii] The United States of America, Canada, Germany and Switzerland removed restrictions on capital movement in 1973, UK in 1979, Japan in 1980 and France & Italy in 1990 (Nayyar 1997, p.20).
[iv] Torre, Yeyati and Schmukler (2002) use the example of dollar trinity and peso trinity to further illustrate the impact of financial globalization on the financial system.
[v] The concept of impossible trinity is pioneered by Mundell in the 60s. According to this principle, a country can only achieve at best 2 of the 3 elements; namely flexible exchange rate, capital account liberalization and autonomous monetary policy.
[vi] Financial dollarization is a term used to describe this situation.
[vii] So far only the United States (dollar) and European Union (Euro) has managed to achieve success in monetary union.
[viii] For every 18 months, the processing speed and computing power of microprocessor doubles by Moore's Law. Rapid improvement in communication technology has increased from a speed of 300 BPS in the form of twisted wire to 10 GBPS in the form of fibre optics (Laudon 2000, p.128 & 267).
[ix] CLOB was established in Singapore to trade in Malaysian listed shares. It was finally abolished following the imposition of the capital control by the Malaysian government in 1998.
[x] [x] Broz (1997) presented evidence in the successful implementation of capital control in countries like France and Germany before 1914.
[xi] Banks are granted a trading charter by the supervisory authority where they were first incorporated
[xii] Among them are the ERM 1992 crisis, Mexican Peso 1994 crisis, Asian currency crisis 1997-1998, Brazilian Real crisis 1998, Russian sovereign debt crisis 1998 and Argentina 2002-2003 crisis.
[xiii] Credit crunch developed as banks and investors cut down their exposure to SEA region at the height of the Asian Currency Crisis in 1997-1998.
[xiv] During the Asian currency crisis HK dollar peg to the US dollar withstood the pressure of speculator and hedge fund. Impact on Singapore's economy was minimal. In fact, it was a beneficiary from fund outflow from neighbouring countries like Malaysia and Indonesia. US financial markets reacted adversely to the crisis in Russia in 1998 but soon rebounded convincingly.
[xv] Momentum trading is defined as a strategy to rapidly buy assets as they appreciate and sell down assets as they decline through a series of short selling activities (IMF 2003, p.48).
[xvi] Borrowers have an incentive to exaggerate its potential earnings to secure more credit if banks are not well versed with its business operations.
[xvii] Recent events are the Asian Currency Crisis 1997, US technology bust in 1999, Enron and World Communication financial scandals.

[xviii] This type of decision-making is called adverse selection. Bank Bumiputera has be to bail out three times by the Malaysian government through Petronas before being finally merged with Bank of Commerce during a banking consolidation exercise in 2001. MBF was taken over the same year by Bank Negara Malaysia.

[xix] For countries that were under the bailout program of the IMF, the loss of autonomy on monetary and fiscal policy was absolute

[xx] EuroRinggit was Malaysian Ringgit currency offered offshore. Hence, these off shores deposits from the perspective of domestic financial regulator and Bank Negara Malaysia are beyond their control and influence

[xxi] This must be supported by a sound contractual and regulatory institution as part of the blessed trinity theory in the study of Torre, Yeyati and Schmukler (2002).

The Determinant of Foreign Direct Investment:
Some Empirical Evidence of ASEAN Countries

Wong Hock Tsen
School of Business and Economics,
Universiti Malaysia Sabah,
Locked Bag No. 2073, 88999 Kota Kinabalu, Sabah, Malaysia

ABSTRACT

The study investigates the determination of foreign direct investment (FDI) in ASEAN countries, namely Indonesia, Malaysia, the Philippines, Singapore and Thailand. For ASEAN countries as a group, the results show that the market size is found to have a significant positive impact on FDI. The formation of ASEAN free trade area (AFTA) and Asian financial crisis, 1997-1998 are not found to have a significant impact on FDI. For each of ASEAN countries, the result shows about the same conclusion as the result for ASEAN countries as a group, but various across countries. Market seeking FDI is an important type of FDI in ASEAN countries. Moreover, there is no simple generalisation of the determination of FDI, which implies the determination of FDI to be justified on a case-by-case basis.

INTRODUCTION

There are many definitions for foreign direct investment (FDI). Generally, FDI is defined as the long-run investment made by a non-resident entity, as an individual or an organisation in a non-resident economy where the non-resident entity has some sense of controlling over the investment. United Nations Conference on Trade and Development (UNCTAD) defines FDI as an investment involving a long-term relationship and reflecting a lasting interest and control by a resident entity in one economy in an enterprise resident in an economy other than that of the resident entity. FDI implies that the investor exerts a significant degree of influence on the management of the enterprise resident in the other economy. FDI involves both the initial transaction between the two entities and all subsequent transactions between them and among foreign affiliates. On the other hand, International Monetary Fund (IMF) emphasises on the ownership of the non-resident entity over the investment 10 percent or more of equity of an entity as FDI. This guideline aims to dividing between FDI and portfolio investment in the form of shareholdings. FDI has three components, namely equity capital, reinvested earnings and intra-company loans. FDI can be wholly owned through acquisitions, greenfield or joint ventures (Chadee and Rose, 2003).

In the recent years, it is generally agreed that FDI could contribute to economic growth and development of the recipient economy. For developing countries (DCs) in particular, FDI is an important source of capital, technology, management know-how and productivity. Moreover, FDI contributes to industrial development, various employment opportunities and trade volume (UNCTAD, 1993: 12). FDI is also more stable in comparison with other forms of foreign capital, with a longer-term commitment to the recipient economy. Asian financial crisis, 1997-1998 shows that other forms of foreign capital, such as portfolio investment and loan reduced significantly during the crisis in most of affected countries while FDI remained positively (Dutt, 1998: 48-51). FDI is motivated by the long-term prospects of the investors for making profits in production activities that they directly control. On the other hand, foreign portfolio investment and loan are usually motivated by short-term profit considerations. FDI is the largest source of external finance for DCs. The stock of FDI of DCs amounted to about one third of their gross domestic product (GDP), compared to just 10 per cent in 1980 (http://www.unctad.org).

FDI is an important source of technology transfer. Technology is crucial for DCs and is shown in the endogenous growth models that technology contributes to economic development (Romer, 2001). In the endogenous growth models, technology could be transferred to DCs through the imitation and importation of high-technology goods and inputs, the mobility of human capital internationally and FDI. The nature of multinational corporations (MNCs) in dissemination of technology has been discussed in several studies. MNCs generally have advantages of more advanced technology, which may be disseminated in the recipient economy through, for example the adoption of the advanced technology by competing firms, the training of workers and the development of infrastructure (Nyatepe-Coo, 1998: 88; Markusen and Venables, 1999).

FDI may increase the productive capacity of an economy in many ways. Foreign firms in general are more productive, which stimulates competition in the domestic market, at least in highly concentrated industries. Therefore, productivity of the economy is expected to be raised (Lim, 2001: 3). FDI may also increase the

productive capacity of the economy through human capital formation or the development of activities based on natural resources. The latter is called backward linkages of FDI (UNCTAD, 2001). FDI has been and will remain a major force in regional industrial restructuring (Chi-Hung, 1996: 157). FDI seems to increase industrial output, generating employment and adding tax revenue (Zhang, 2001: 682).

Nevertheless, the presence of FDI in the recipient economy may not leave without any negative impact on the recipient economy. FDI may cause deficit in the balance of payments of the recipient economy if FDI rises to substantial reverse flows in the form of remittances of profits and dividends and or if MNCs obtain substantial tax or other concessions from the recipient economy (Phang, 1998; Ramirez, 2000: 145). FDI may suppress domestic firms and use their advantages in technology to drive out domestic competitors (Zhang, 2001: 684). Moreover, the role of FDI as a source of technology transfer is queried in some studies, which argue the less importance of technological progress in contributing to economic growth. For example, Kim and Lau (1994) found that technological progress was relatively unimportant as a source of growth of the four East Asian newly industrialising economies (NIEs). The most important source of economic growth of the East Asian NIEs was capital accumulation, accounting for 48-72 percent of their economic growth, in contrast to France, West Germany, Japan, the United Kingdom and the United States, where technical progress has played the most important role, accounting for 46-71 percent of their economic growth.

FDI is one of important factors that leads to the globalisation of the world economy. FDI contributes to strong economic links between countries (Chung-Sok and Jung-Soo, 1998: 124). Generally, FDI in the world increases over time. In 1970, FDI in the world was US dollar 12,586 million, increased to US dollar 54,945 million in 1980 and US dollar 202,782 million in 1990. In 2001, FDI in the world was US dollar 735,146 million. Developed countries remain the main destination of FDI while DCs still receive a small amount of FDI (UNCTAD, 2002). Nonetheless, the geography of FDI has been changing. Although, developed countries such as those of Western Europe and North America have been remaining the main destination of FDI, but DCs such as those of South, East, and Southeast Asia, have increasingly been the recipients of FDI. China has been a major recipient economy for FDI. Currently, China is the second largest recipient of FDI in the world, and the largest recipient among DCs (Chadee and Rose, 2003). For ASEAN countries, Singapore, Malaysia and Thailand have been receiving quit substantial amounts of FDI in the region (Chung-Sok and Jung-Soo, 1998: 125).

Generally, the determination of FDI in DCs is not well understood. Pan (2003) examined the determination of FDI in China and reported that some of the factors generally viewed, as important determinants for FDI in developed countries are not important in China. Thus, this raises the question regarding the generalisation of the determination of FDI (Chadee and Rose, 2003). Moreover, identifying a set of determinants for FDI is important for policy markers in the competitive world of attracting FDI. Thus, the main aims of the study are to investigate the determination of FDI in ASEAN countries as a group and also the determination of FDI in each of ASEAN countries. For ASEAN countries as a group, the estimations are carried-out by using the panel estimator while for each country of ASEAN countries the estimations are carried-out by using the ordinary least squares (OLS) estimator. The period of study is generally from 1972 to 2002.

The rest of the article is organised as follows: Section 2 gives an explanation of ASEAN and FDI in ASEAN countries. Section 3 provides a literature review of the determination of FDI. Section 4 explains the empirical estimations and data. Section 5 discusses the empirical results. Section 6 gives some concluding remarks.

ASEAN AND FDI

ASEAN was established on 8 August 1967 in Bangkok. Its five founder members are Indonesia, Malaysia, the Philippines, Singapore, and Thailand. Brunei Darussalam joined on 8 January 1984, Viet Nam on 28 July 1995, Laos and Myanmar on 23 July 1997, and Cambodia on 30 April 1999. The initial objectives of ASEAN were to foster regional security and intra-regional dispute resolution issues (http://www.aseansec.org/). ASEAN, a total area of 4,495,493 million square kilometres, has a combined population of about 500 million and a combined GDP of US dollar 737.48 million in 2000. The average GDP per capital of ASEAN was US dollar 1,474, varying from US dollar 315 in Lao to US dollar 25,864 in Singapore. In 2000, real GDP grow rates in ASEAN were impressive, ranges from 3 percent in Brunei Darussalam to 9.9 per cent in Singapore. Growth rate of consumer price indices were rather stable in most of ASEAN countries. Unemployment rates in ASEAN vary across countries, from 3.1 percent in Singapore and Malaysia, respectively to 7.4 percent in Viet Nam (UNCTAD).

In the 1970s, economic goals became an important agenda for ASEAN. In 1972, a United Nations team of experts recommended that ASEAN countries take a number of measures, which would accelerate their industrial development on a regional scale through closer regional economic integration. The rational is that a larger ASEAN market, in the form of an ASEAN free trade area would encourage industrial development and intra-

regional trade. In 1977, a preferential trading agreement (PTA) is signed to reduce tariffs on goods meeting rules of origin requirements with the aim to encourage closer regional co-operation through an expansion of intra-regional trade (Tan, 1996: 139-140). The PTA was not very successful, amongst others, because its narrow commodity coverage and the half-hearted nature of the implemented process. The industrial cooperation schemes are also not very successful, amongst others, the precedence of national over regional interests and lack of initiative and participate from private sector (Yamazawa, 1992: 1525; Athukorala and Menon, 1996; Tan, 1996: 140-155).

In January 1992, it was agreed to reactive integration of ASEAN by establishing an ASEAN free trade area (AFTA) within 15 years. The idea was partly in response to the slow progress of effective trade liberalisation under the PTA and the formation of North American Free Trade Agreement (NAFTA) and the unification of the European Union market. Also, there was alert the possibility of the diversion of FDI away from Southeast Asia towards North America and Western Europe (Tan, 1996: 159-160). Under AFTA, all ASEAN countries participate in a Common Effective Preferential Tariff (CEPT) scheme. Under the CEPT scheme, the countries of ASEAN would reduce intra-regional tariffs on all manufactured items including capital goods and processed agricultural products and remove non-tariff barriers over a 15-year period commencing 1 January 1993. However, in view of the economic challenges, the ASEAN Economic Ministers meeting on 22-23 September 1994 in Chiangmai, Thailand agreed to shorten the time frame for the realisation of the AFTA from 15 to 10 years, finishing by 1 January 2003 instead of 2008, and to include unprocessed agricultural products (UAPs) into the CEPT scheme (Tan, 1996: 160).

ASEAN, as a group, receives a relatively small amount of FDI in the world. In 1970, ASEAN received 3 percent of FDI in the world, increased to 4.4 percent in 1980 and 6.3 percent in 1990. After Asian financial crisis, ASEAN received a much smaller amount of FDI in the world, 1.8 percent in 1999 and 2001, respectively. Nevertheless, ASEAN, as a group, receives a substantial amount of FDI among DCs. In 1970, ASEAN received 12 percent of FDI in DCs, increased to 28.8 percent in 1980 and 33.9 percent in 1990. In 2001, ASEAN received 6.5 percent of FDI in DCs. Generally, FDI in ASEAN had been increasing prior to Asian financial crisis and has been declining after the crisis. In 1970, FDI in ASEAN was US dollar 374 million, increased to US dollar 2,415 million in 1980 and US dollar 12,740 million in 1990. In 1995, FDI in ASEAN was about twice the amount of FDI in 1990, i.e. US dollar 25,367 million. After the crisis, FDI in ASEAN has been declining. In 1999, FDI in ASEAN was US dollar 19,691 million and decreased to US dollar 13,240 million in 2001 (Table 1).

Table 1: FDI: A Comparison (US Dollar, Million)

FDI in ASEAN is concentrated in few countries and the rest receive a small amount of FDI. Singapore, Thailand and Malaysia receive most of FDI in ASEAN. On the other hand, the Philippine receives fairly amounts of FDI. Indonesia receives a large amount of FDI prior to the crisis. After the crisis, Indonesia experiences FDI outflows more than FDI inflows (Table 2). The unequally distributed of FDI in ASEAN is partly because of policy towards FDI and also infrastructure facilities. Generally, countries receive less FDI are those late in adopting a more liberal policy towards FDI, lack of basic infrastructure facilities and political instability. Moreover, these countries are lack of semi-skilled and skilled labour.

THE DETERMINATION OF FDI

Shatz and Venables (2000) classify FDI into two main categories, namely vertical FDI and horizontal FDI. Vertical FDI occurs when MNCs fragment the production process internationally, locating each stage of production in a country. The main motive is to minimise the costs of production, which could be labour of different skill levels, primary commodities, intermediate goods, or even access to externalities, such as knowledge spillovers. Vertical FDI is usually trade creating, since products at different stages of production are shipped among different locations. Horizontal FDI occurs when MNCs operate the same production activities in multiple countries. The motive could be to reduce costs, such as transportation costs and tariffs or to improve the competitive position of firm in the market. This type of FDI is mainly to serve local markets and therefore substitutes for trade, since parent firms replace exports with local production. The distinction between vertical FDI and horizontal FDI is not clear when one plant may serve both functions (Shatz and Venables, 2000). Moreover, the motives for foreign production may change over time (Dunning, 1993: 57). The boundaries between different types of FDI become not clear as all FDI is seen as part of an overall strategy of enhancing competitiveness. This strategy therefore makes it increasingly difficult to point to a single locational determinant (Noorbakhsh *et al.*, 2001: 1595).

The literature of the determination of FDI proposes few important factors that affect FDI, such as the market size, openness to international trade, economic integration and costs of production. Some of the factors are likely to affect all types of FDI. Nevertheless, the different strategic objectives implicit in vertical FDI and horizontal FDI suggest that some of factors may affect one type of FDI more than the other (Lim, 2001: 12). Generally, the larger the market size of the host country, the more attractive it is to FDI. A large market size is conducive to increase in demand for the products and services. Moreover, a large market size allows the achievement of economies of scale (Caves, 1971; Erdal and Tatoglu, 2002). A large market size will encourage horizontal FDI. Nevertheless, vertical FDI is indifferent to the market size of the host country. The net impact of market size on FDI is likely to be positive. Therefore, the relationship between FDI and the larger the market size is expected to be positive (Lim, 2001). The proxy for the market size in the literature of the determination of FDI is usually the real GDP, the real GDP per capita or population. Most of studies in the literature suggest that the market size is found mostly to have a significant positive impact on FDI (Chung-Sok and Jung-Soo, 1998; Billington, 1999; Cheng and Kwan, 2000; Shatz and Venables, 2000). This partly reflects the fact that most of the world's FDI is horizontal in nature (Lim, 2001).

Countries, which adopt an export promotion policy usually, reveal a high degree of openness. Thus, openness to international trade is used to capture that factor (Chung-Sok and Jung-Soo, 1998: 134). A free trade area is a form of EI. In a free trade area, member countries remove tariffs among themselves and each of member countries determines its own tariff towards non-member countries (Rodgers, 1998: 213; Appleyard and Field, 2001: 351-362). Economic integration creates a larger market (Motta and Norman, 1996: 758). Thus, economic integration is a way to attract FDI for local production within the integrating area. A larger market allows firm to increase its production to achieve economic of scale, which increases productivity and reduces costs of production. A larger market can accommodate more firms. Thus, a firm may face higher competition, which would encourage efficiency. Alternatively, firm may seek strategic alliances or merge with another firm to meet a more competitive environment after trade barriers are removed.

The lower the costs of production, the more attractive it is to FDI. Therefore, the higher the wage costs is likely to defer FDI and the relationship between FDI and the wage costs is expected to be negative. Nevertheless, empirical findings about the significance of the relationship is mixed (Billington, 1999; Lim, 2001). Cheng and Kwan (2000) found the real wage costs has a significant negative impact on FDI in China. Interest rate is a measure of the cost of capital. A higher interest rate implies more costly for investment and therefore, the higher the interest rate is likely to defer FDI and the relationship between FDI and the interest rate is expected to be negative. Love and Lage-Hidalgo (2000) and Erdal and Tatoglu (2002), amongst others found that an increase in the interest rate leads to a decrease in FDI.

The literature suggests that in addition to the variables selected above, there are other factors, which could have an important impact on FDI such as incentives (fiscal and monetary), special economic zone (such as free trade or exports processing zone), business or investment climate, economic distance or transportation cost and political stability (Noorbakhsh *et al.*, 2001). Nevertheless, those factors are empirically difficult to be investigated.

Chung-Sok and Jung-Soo (1988) examined the determination of FDI in four Asian NIEs, ASEAN-4 and China. The study uses a cross-country model for heteroscedasticity consistent OLS estimation and uses the averages of variables for each country over the period 1985-1994. Moreover, the study pools the time series and cross-section data over the period 1987-1994 and employs the OLS estimator. The results amongst others show that openness to international trade is found to be the most important factor for the determination of FDI, which reveals the dynamic nature of the economies created by the export promotion policy adopted by the government. The GDP growth rate is shown to have a negative impact on FDI. Nonetheless, population as a proxy for the market size is found to have a significant positive impact on FDI. The growth rate of wage and the membership in ASEAN are found not to have a significant impact on FDI. On the whole, they concluded that the market size and openness to international trade are more important determinants for FDI than the low wage rate.

Nunnenkamp and Spatz (2002) examined a sample of 28 developing countries over the period 1987-2000. The results show that amongst others there is a significant Spearman correlation between FDI and per capita gross national product (GNP). On the other hand, population and GNP growth are found to be statistically insignificant. However, when regressions were performed separately for the non-traditional factors, in which traditional factors were controls, namely population and per capita GNP, only factor costs produced significant results and, even so, only for the period of 1997-2000.

Carstensen and Toubal (2004) examined the determination of FDI in Central and Eastern European countries. The results show that the traditional determinants such as market potential, low relative unit labour costs, a skilled workforce and relative endowments are found to have a significant impact on FDI. In addition, transitions-specific factors such as the level and method of privatisation and the country risk play important roles in the determination of FDI and help to explain the differing attractiveness of the individual countries to foreign investors.

THE EMPIRICAL ESTIMATION AND DATA

Generally, the determination of FDI is said to be a function of the market size, openness to international trade, the interest rate and the government consumption. In this study, the model to be estimated is specified as:[1]

$$\Delta \, FDI_{it} = \beta_{10} + \beta_{11} \, \Delta \, Y_{it} + \beta_{12} \, \Delta \, O_{it} + \beta_{13} \, \Delta \, R_{it} + \beta_{14} \, DI_{it} + \beta_{15} \, DC_{it} + \beta_{16} \, \Delta \, G_{it} + e_{1,it} \tag{1}$$

where Δ is the first difference operator; FDI_{it} is FDI; Y_{it} is the market size; O_{it} is openness to international trade; R_{it} is the interest rate; DI_{it} is the dummy variable for the formation of AFTA (0 for 1972-1991 and 1 for 1992-2002); DC_{it} is the dummy variable for Asian financial crisis, 1997-1998 (1 for 1997-1998 and 0 for the rest); G_{it} is the government consumption; and $e_{j,it}$ (j = 1, 2) is an error term. For each of ASEAN countries, equation (1) is also estimated, but without the subscript i.

An increase in the market size, openness to international trade or the government consumption would lead to an increase in FDI. Therefore, coefficients of those variables are respectively expected to have a positive sign. On the other hand, an increase in the interest rate would lead to an increase or a decrease in FDI. Thus, the expected sign for the coefficient of the interest rate is to be determined by the data. The coefficient of the dummy variable for the formation of AFTA is expected to have a positive sign while the coefficient of the dummy variable for Asian financial crisis is expected to have a negative sign.

---

[1]The results of the Phillips and Perron (1988) unit root test statistic which are not reported show that generally all the variables are stationary in the first differences.

The study uses panel data. The empirical estimation is carried out by using the random/fixed-effects estimator. The result of random/fixed-effects estimator to be used is determined by the Breusch and Pagan Lagrangian multiplier (LM) test statistic. For the insignificance of the LM test statistic, the result of the random-effects estimator is used. Otherwise, the result of the fixed-effects estimator is used. Nevertheless, only one of the results is to be reported.[2] For each of ASEAN countries, the empirical estimations are carried out by using the OLS estimator.

The sample period is generally from 1972 to 2002. The sample period is chosen subject to the availability of data. The data were obtained from IMF. FDI (FDI_{it}) is expressed as a net basis (capital account credits less debits between direct investors and their foreign affiliates) in a particular year divided by consumer price index (1995=100). The market size (Y_{it}) is expressed as the gross national income divided by GDP deflator (1995=100). Openness to international trade (O_{it}) is expressed as (Exports + Imports) / Nominal GDP. The interest rate (R_{it}) is expressed as the deposit rate divided by consumer price index (1995=100) for Indonesia and Thailand, and as the treasure bill rate divided by consumer price index (1995=100) for Malaysia, the Philippines and Singapore. The government consumption (G_{it}) is expressed by the government consumption divided by consumer price index (1995=100). All the currency values are in US dollar.

EMPIRICAL RESULTS AND DISCUSSIONS

The result of the determination of FDI in ASEAN countries as a group is reported in Table 3. The market size is found to have a significant positive impact on FDI. Other independent variables are found to be statistically insignificant. The results of the determination of FDI in each of ASEAN countries are reported in Table 4. For Indonesia, the market size is found to have a significant positive impact on FDI. On the other hand, Asian financial crisis is found to have a significant negative impact on FDI. Other independent variables are found to be statistically insignificant. For Malaysia and Singapore, the market size is found to have a significant positive impact on FDI. The rest of independent variables are found to be statistically insignificant. For the Philippines, all independent variables are found not have a significant impact on FDI. This may suggest that other factors that affect FDI to be considered. For Thailand, the formation of AFTA is found to have a significant negative impact on FDI. On the other hand, Asian financial crisis is found to have a significant positive impact on FDI.

Note: See Table 3 for explanation.

The finding that the market size is an important factor for the determination of FDI is consistent with the finding of Chung-Sok and Jung-Soo (1988). Nunnenkamp and Spatz (2002), and Carstensen and Toubal (2004), amongst others also reported the importance of the market size in the determination of FDI. On the other hand, the formation of AFTA is found not to have a significant impact on FDI. Chung-Sok and Jung-Soo (1988) also reported that the membership of ASEAN did not contribute to FDI. The impact of Asian financial crisis is generally found not to have a significant adverse impact on FDI in ASEAN countries. This is because FDI is motivated by the long-term prospects of the investors for making profits in production activities that they directly control. However, for Indonesia, the crisis had adversely affected inflows of FDI in that country.

The market size is found to be an important factor for FDI in ASEAN countries, as a group and also each of ASEAN countries, except the Philippines and Thailand. Thus, market-seeking FDI is an important type of FDI in ASEAN countries. The economic growth and stability of the economy are expected to attract more market seeking FDI in ASEAN countries. After Asian financial crisis, most of ASEAN countries achieve a relatively high economic growth and therefore FDI is expected to increase. In other words, as long as economy continues to growth, FDI is expected to increase.

Chadee and Rose (2003) and Pan (2003), amongst others also raised the question of the generalisation of the determination of FDI. Generally, the market size is found to have a significant impact on FDI in the literature of the determination of FDI. For ASEAN countries as a group, the market size is found to have a significant positive impact on FDI. Nonetheless, for each of ASEAN countries, the market size is found to have a significant positive on FDI for Indonesia, Malaysia and Thailand, but not for the Philippines and Thailand. Moreover, most of traditional macroeconomic variables to be considered important for the determination of FDI in the literature are found not important for most of ASEAN countries. Thus, there is no simple generalisation of the determination of FDI. The finding suggests that the determination of FDI should be considered on a case-by-case basic.

The study focuses on the importance of traditional macroeconomic variables on FDI. Nonetheless, other non-traditional macroeconomic variables such as human capital, infrastructure, transparency of the government and political stability are important for the determination of FDI, which are to be considered. Nunnenkamp and Spatz (2002) and Carstensen and Toubal (2004), amongst others considered other non-traditional macroeconomic variables on FDI.

CONCLUDING REMARKS

The aims of the study are to investigate the determination of FDI in ASEAN countries as a group and also the determination of FDI in each of ASEAN countries. For ASEAN countries as a group, the result shows that the market size is found to have an important impact on FDI. Factors such as AFTA and Asian financial crisis are found not to have a significant impact on FDI. For each of ASEAN countries, the result shows about the same conclusion as those obtained for ASEAN countries as a group, but various across countries. Market seeking FDI is an important type of FDI in ASEAN countries. Also, there is no simple generalisation of the determination of FDI. Nonetheless, more studies should be carried-out to clarify the finding.

ABSTRACT

This study examines the international evidence on long-run neutrality (LRN) of money based on low frequency data from five emerging ASEAN economies, namely, Indonesia, Malaysia, the Philippines, Singapore, and Thailand, using a nonstructural reduced-form bivariate ARIMA model proposed by Fisher and Seater (1993). Empirical evidence shows that the classical proposition cannot be rejected with respect to real export except for Thailand. However, the LRN test results are not robust to a change in the country under study with respect to real output. The narrow monetary aggregate seems to have greater influential impact towards the Indonesia, Malaysia, and Thailand economic activities as compared to the other two countries.

INTRODUCTION

The study on the relationship between money supply and real economic activity has created much debate both theoretically and empirically. Researchers try to examine the consequences of innovation in money supply towards real macroeconomics variables, by investigating different countries at different time period with the assistance of various econometric techniques. The controversy over this issue, however, remains unsolved. The debate regarding the role of money in the economy finds its origins in the classical quantity theory of money. It is believed that real economic variables in the economy are determined by real forces and those monetary forces only affected nominal quantities. The inability of changes in the stock of money to affect real economic activity except for the general price level is called the long-run neutrality (LRN) of money.

The classical economists believed that the markets could always be in the most efficient condition without the intervention of government. Supply should always equal demand as the price levels can be adjusted immediately and completely to the shocks in the economy. Therefore, the role of money has been relegated to the background, and money is said to be long run neutral in the classical world. In contrary, the Keynesian economists propose that government should take an active role in the markets. They do not believe on the self-correcting mechanism in the markets, as prices are somewhat rigid in the present of menu costs and efficiency wages. Consequently, the government could use discretionary monetary policy to moderate fluctuations in the business cycle. Thus, Keynesian economists contend that money is non-neutral in the long run.

In view of the theoretical controversial over the role of money, the empirical work should be carried out to provide a better understanding on how money affect output in different countries and level of development (i.e. developed versus less developed economies). Interestingly, the empirical evidence on LRN has been in a state of flux. While some studies found supportive evidence on LRN proposition, others discover that money supply do have influential effects on real economic activity in the short as well as long-run. Furthermore, most of the empirical studies on the LRN were conducted for one or a group of developed countries, with little attention given to the less developed emerging economies.

The objective of this study is to provide some empirical evidence on the LRN of money supply in five ASEAN developing countries of Indonesia, Malaysia, the Philippines, Singapore, and Thailand. Since earlier studies on monetary neutrality in Asian developing countries are limited, our study helps to add knowledge on this area. In order to test for the quantity theoretic proposition, we utilize the bivariate reduced-form ARIMA model, proposed by Fisher and Seater (1993, hereafter FS). Specifically, we examine the long run effect of the permanent shocks of narrow money supply on real export and real output in these ASEAN economies.

The remainder of this paper is organized as follows. Section II provides the relevant literature on LRN. The methodology and data used in the analysis will be discussed in Section III. Section IV presents the empirical findings, and concluding remarks are given in Section V.

REVIEW ON LONG-RUN NEUTRALITY OF MONEY

The classical definition of LRN of money implies that the autonomous changes in the level of money supply do not have long run effect on the level of real economic activity. There are many approaches to test for LRN propositions, and a leading method is given by FS. They derive a simple and relatively structural free model for testing the classical hypothesis. In their writing in the American Economic Review (1993, pp. 402), FS state that: "*Because LRN and LRSN[1] do not depend on the short-run dynamics of the economy, structural details that are important for many issues are not relevant to LRN and LRSN. It is desirable, therefore, to have tests of LRN and LRSN that are relatively structure-free. A convenient setting for nonstructureal tests is provided by a multivariate ARIMA model*". The simplicity of FS's LRN test has lead to voluminous empirical studies of the consequences of money supply shocks on real economic activity in both developed and developing countries.

Using US annual observations from 1869 to 1975, FS found that the LRN held with respect to prices and nominal income, but it is rejected with respect to real income. Boschen and Otrok (1994) re-examine the empirical study by FS using the same data set (updated by them to include the 1976-92 period). They point out that the rejection of LRN by FS is due to the inclusion of the Great Depression decade of 1930-39. On the other side, Haug and Lucas (1997) found support for the LRN in Canada. They further claim that bank failures alone should not entirely be accounted for the rejection of LRN when data from the period of the 1930's are included in the sample.

Malliaropulos (1995) provides empirical evidence on the LRN in UK based on FS's model. Using quarterly data on money supply (M4), consumer prices, real GDP, nominal GDP, and equity prices, Malliaropulos found that money does not matter with respect to real GDP and real equity prices in the long run. Nevertheless, permanent innovations in money stock do have transitory real effects on UK economy for the period under study. With the same methodology and using Backus and Kehoe (1992) long, low-frequency data set, Serletis and Krause (1996) also found supportive evidence of the quantity theoretic proposition for Australia, Canada, Denmark, Italy, UK and US.

For the Mexican economy, for the period 1932 to 1992, Wallace (1999) found out that the LRN proposition holds for both money supply, M1 and M2. By updating the Mexican data set to 2000, Noriega (2000), however, discovers that LRN only holds for M2 when he re-examines Wallace's LRN test using Pantula's (1989) sequential unit root tests. Noriega, therefore, claims that the LRN tests are sensitive to both the sample size and the testing procedure used. In particular, it is especially important to conduct a proper unit root test in order to find out the "right" order of integration.

Leong and McAleer (2000) utilise both quarterly seasonally adjusted and unadjusted Australian real GDP and nominal money supply to test the neutrality hypothesis. They found that the neutrality tests are sensitive to the type of money supply used. While the LRN hypothesis is supported using narrow money supply, M1; it is rejected when M3, a broader measure of money is used. They further claim that this disparity might be due to the recent trends and developments in the money and credit markets in Australia.

Noriega (2003) considers the LRN tests based on FS model using low-frequency data on real output and money aggregates for Argentina, Australia, Brazil, Canada, Denmark, Italy, Mexico, Sweden, UK, and US. Noriega claims that the unit root tests are not robust with different testing methodologies. M2 is found to be LRN with respect to real output in Brazil, Canada, Sweden, and Mexico. For Argentina, Australia, Italy, Mexico, and the UK, M1 does matter. Apart from that, Noriega found no direct evidence in favor of LRN based on unit root tests on the data of Denmark and the US.

---

[1] LRSN refer to long-run superneutrality of money.

METHODOLOGY AND DATA

In this study, we employ the dynamic simultaneous equation model developed by FS to test for the LRN proposition with respect to real output and real export in five ASEAN economies using the narrow money supply, M1. Let m be log money stock and y the log of real economic activity. The model is given as follows:

$$a(L)\Delta^{\langle m\rangle}m_t = b(L)\Delta^{\langle y\rangle}y_t + u_t$$

(1)

$$d(L)\Delta^{\langle y\rangle}y_t = c(L)\Delta^{\langle m\rangle}m_t + w_t$$

where Δ represent the first differences, $a(L)$, $b(L)$, $c(L)$ and $d(L)$ are distributed lag polynomials in the lag operator L, with $a_0 = d_0 = 1$, and b_0 and c_0 are not restricted. $\langle m\rangle$ and $\langle y\rangle$ are the orders of integration of the money supply and real economic activity.

Let $x_t \equiv \Delta^i m_t$ and $z_t \equiv \Delta^j y_t$, where i and j equal 0 or 1, FS then defined the LRN in terms of the long-run derivative (LRD) of z with respect to a permanent change in x as follows:

$$LRD_{z,x} \equiv \lim_{k\to\infty} \frac{\partial z_{t+k}/\partial u_t}{\partial x_{t+k}/\partial u_t}$$

(2)

where $\lim_{k\to\infty} \partial x_{t+k}/\partial u_t \neq 0$. If $\lim_{k\to\infty} \partial x_{t+k}/\partial u_t = 0$, there will be no permanent changes in the level of money and thus the LRN proposition cannot be tested. $LRD_{z,x}$ expresses the ultimate effect of an exogenous money disturbance on z relative to that disturbance's ultimate effect on x. As such, the specific value of the $LRD_{z,x}$ depends on $\langle x\rangle$ and $\langle z\rangle$.

If the order of integration of real and monetary variables are both at least equal to or greater then one, the $LRD_{z,x}$ can be measured using the impulse response representation for x and z which is given by the solution of Equation (1). A special case occur when $\langle x\rangle = \langle z\rangle = 1$, where $LRD_{z,x}$ becomes $c(1)/d(1)$, which is a measures of the relationship between the permanent changes in real economic activity with respect to permanent stochastic changes in money aggregate. LRN requires that $LRD_{z,x} = 1$ if z is a nominal variable, and $LRD_{z,x} = 0$ if z is a real variable.

Assuming the money supply is exogenous and the error term is *iid* $(0,\sigma^2)$, the term $c(1)/d(1)$ is the Bartlett estimator of frequency-zero coefficient in a regression of $\Delta^{\langle y\rangle}y_t$ on $\Delta^{\langle m\rangle}m_t$. An estimate of $c(1)/d(1)$ is given by $\lim_{k\to\infty}\beta_k$, where β_k is the slope coefficient from the following OLS regression:

$$\left[\sum_{j=0}^{k}\Delta^{\langle y\rangle}y_{t-j}\right] = \alpha_k + \beta_k\left[\sum_{j=0}^{k}\Delta^{\langle m\rangle}m_{t-j}\right] + \varepsilon_{kt}$$

(3)

When $\langle m\rangle = \langle y\rangle = 1$, Equation (3) becomes:

$$(y_t - y_{t-k-1}) = \alpha_k + \beta_k(m_t - m_{t-k-1}) + \varepsilon_{kt}$$

(4)

The null hypothesis of LRN is $\beta_k = 0$. The non-rejection of the null hypothesis indicates the data supports the LRN proposition.

Data Descriptions

This study makes use of annual data spanning from 1970 to 2001 on narrow money supply (M1), real export and real output from five emerging ASEAN economies, namely Indonesia, Malaysia, the Philippines, Singapore, and Thailand. All data were collected from various issues of the *International Financial Statistics* published by International Monetary Fund (IMF). All series were in the natural logarithm form.

THE EMPIRICAL RESULTS

Time Series Properties of the Data

Following FS, the order of integration of money supply should be at least equal to one for LRN tests to make sense, or there will be no stochastic permanent innovations in the level of money that can affect the real economic variables. In particular, LRN tests require both nominal and real variables are at least integrated of order one and of the same order of integration. As such, the first step in conducting the LRN tests is to determine whether the time series are actually non-stationary and the degree to which they are integrated if they do not contain a unit root. To do so, we utilize the Augmented Dickey-Fuller (ADF) (Said and Dickey, 1984) unit root tests to check for the non-stationarity property of the data. Since the unit root tests results are sensitive to different values of the autoregressive lag length, the selection rule of the truncation lag parameter is crucial in determining the order of integration of the data. In this study, the optimal lag length is chosen based on the Schwartz Information Criterion (SIC) to ensure the errors are white noise.

Table 1 presents the ADF *t*-statistics that describing the stationary properties of M1, real export and real output in the ASEAN-5 countries. We report the results, which contain drift and a deterministic trend for the series in levels and drift without a deterministic trend for the series in first differences. Then, we compare the results with the critical value provided by MacKinnon (1991). As shown in Table 1, we fail to reject the null hypothesis of a unit root in their levels, indicating that the series are not in the trend-stationary process. In their first differences, however, all series appear to be stationary. In other words, all series are said to be integrated of order one, that is $I(1)$, which in term implies that the LRN restriction $c(1)/d(1)$ is testable.

Table 1: ADF Unit Root Test Results

Country & Series	Level with trend		First difference without trend	
	Test statistic	Lag length	Test statistic	Lag length

Note: Asterisks (**) and (***) indicate significant at the 5% and 1% level respectively.

Serletis and Koustas (1998) and Koustas and Serletis (1999) contend that the LRN tests are inefficient in the presence of cointegration. If money supply and real macro variables have long-run equilibrium relationship, then money should not be considered as neutral in the long run. Subsequently, the second step is to confirm the condition, that is, meaningful for the LRN tests by finding the cointegrated relations within the blocks of real and monetary variables. Table 2 reports the Johansen and Juselius (1990) maximum likelihood (ML) cointegration tests results. The required numbers of lag (l) in the VARs are selected by means of the Schwarz Bayesian Criterion (SBC). Empirical results show that both trace and λ-max statistics are insignificant at five percent level, implying that there is no common trend exists within the two-variable set data for all the country under study.

The Long-Run Neutrality Test Results

Results on the properties of time series from the unit root and cointegration tests suggest that all the countries confirm the conditions require under the LRN tests. Equation (4) is then estimated for each of the country with k equal 1-11. The lag length k is chosen by $n/3$, where n is the number of observations. The error term, ε_{kt}, from the regression for the various lags may be non-spherical, possibly leading to biased t-ratios and outcomes of the LRN tests. In view of that, following FS, the standard error of β_k has been calculated using the Newey and West (1987) procedure to correct for heteroskedasticity and autocorrelation. Estimated results of Equation (4) are then presented in the tabulate form for the five countries under study. We present the values of estimated coefficients (β_k), Newey-West standard error (SE_k), t-statistic of null hypothesis (t_k), and the marginal significance level of null hypothesis (p-value). The null hypothesis is $\beta_k = 0$ for y is a real variable.

		r ≤ 1	r = 2	0.39	8.07	r ≤ 1	r = 2	0.39	8.07

Notes: Asterisks (**) indicate significant at the 5% level. Critical values are taken from Table 1, Osterwald-Lenum (1992). Lag selection is based on SBC.

LRN of M1 with respect to real output: Results from estimating Equation (4) are reported in Tables 3 (a) to 7 (a). A mixture of empirical results has detected in this study that the LRN proposition is supported for some countries but it is rejected in others. We found that the null hypothesis of slope coefficient β_k equals zero cannot be rejected at all k values for the Philippines and Singapore. Hence, we conclude that M1 does not matter in these two countries. However, the estimated coefficients are positive and statistically significant from zero at five percent significance level at $k < 8$ for Malaysia, at $2 < k < 7$ for Thailand and at all k values for Indonesia. This implies that permanent changes in narrow money supply do have positive transitory effects, in short to medium term, on the level of real output in Malaysia and Thailand. For Indonesia, M1 can be treated as an independent stimulus to the real output in the long run.

LRN of M1 with respect to real export: Generally, the classical proposition is more supported when real export and M1 are used. The estimated results of running Equation (4) are presented in Tables 3 (b) to 7 (b). Except for Thailand, the slope coefficients for money supply are all statistically insignificant at the conventional level. This means that the narrow money supply might not be the primer engine for the rapid growth of export in these four ASEAN countries during the period under study. In other words, the financial-led export growth hypothesis does not hold in the context of narrow monetary aggregate. For Thailand, however, the null hypothesis of $\beta_k = 0$ can be rejected at all k values that are greater than 6, indicating the real export activity is not neutral to the innovations in narrow monetary forces.

CONCLUSION

In this study, we employ the bivariate reduced-form ARIMA model proposed by FS to give some empirical evidence on the LRN of monetary policy in five ASEAN developing economies. The ADF unit root tests provide direct evidence in favour of the LRN tests in these ASEAN countries. Empirical results further show that the LRN is generally holds with respect to real export except for Thailand. With respect to real output, however, the narrow money supply seems to have greater influential consequences on the economies of Indonesia. Nevertheless, for other ASEAN countries, in particular, the M1 has short to medium term positive transitory real effect on Malaysia and Thailand. In view of this, we conclude that LRN is a general feature of the five ASEAN emerging economies. Our findings are consistent with Moosa (1997), who found supportive evidence of LRN in the context of a developing economy, India.

The inability of monetary policy to affect real economic activities is probably due to the recent development in the financial markets in the Asian emerging economies. Researches show that the financial liberalization in any economy will create new problems for the monetary authorities to effectively pursue their monetary policy. For instance, Tseng and Corker (1993) have conducted an empirical study on nine Asian developing countries, which include Indonesia, Malaysia, Myanmar, Nepal, the Philippines, Singapore, Sri Lanka, South Korea, and Thailand. They have pointed out that "*Financial liberalization brought many new challenges for the monetary authorities of these countries,... In particular, financial liberalization has altered the relationship between money, income, and interest rates, complicating the interpretation of developments in monetary aggregates.*"
Although financial deregulation and innovation can enhance the effectiveness of monetary policy, it might also distort the relationship between monetary aggregates and other macroeconomic variables. As the financial markets developed, the role of non-bank institutions becomes more apparent, and the shift of money to the interest-bearing financial assets offered by the non-bank institutions will subsequently affect the stability of money demand function. Laumas and Porter-Hudak (1986) argue that a measurable and stable money demand function is necessary for the monetary policy to be effective. As a result of increasingly difficult to target on a particular monetary aggregate in order to attain the ultimate objectives, some of the monetary authorities in Asian developing countries have shifted away from monetary targeting to other intermediate targets such as inflation targeting and interest rate targeting.

ABSTRACT
This study attempts to detect the presence of long run money-income relationship using two different approaches that is the parametric and non-parametric procedures. In this paper, the widely used Johansen (1988, 1991) cointegration test and the Bierens (1997c) non-parametric cointegration tests are employed. The findings show that while the standard Johansen cointegration test reveals that most of the monetary aggregate measures are not cointegrated with nominal income, clear evidence of cointegration are shown by the Bierens's non-parametric approach, which contrast sharply with a number of existing evidence obtained from the standard cointegration tests. The empirical findings suggest that the potential policy role of monetary aggregate cannot be ruled out.

INTRODUCTION

Until the mid-1990s, the Malaysia's monetary policy strategy had been based on targeting of monetary aggregates. However, far-reaching changes in the economy and financial system have led to the breakdown of the relationship between monetary aggregate and goal variables such as inflation and nominal income. Consequently, towards mid-1990s, the central bank of Malaysia (Bank Negara Malaysia, BNM) shifted its focus from monetary targeting to interest rate targeting[1].

Similar experiences have also been observed in other developing economies. The so-called 'velocity instability' problem – has been the major motivation for central banks to either de-emphasized their monetary aggregate targets or dropped them altogether, in some cases returning to interest-based policy procedure and in others seeking out new organizing principles like direct inflation targets[2].

The question most obviously raised by policy makers evolving the use of such money growth target over the past two decades is how useful are monetary aggregates as intermediate targets or information variables in the conduct of monetary policy. In principle, there are various potential uses for monetary aggregates (see, Friedman, 1996). Monetary aggregates may be useful if they contain information about the underlying contemporaneous state of the economy, by providing a guide for the conduct of monetary policy. If the policy role involves expectations of future variables, then, money can be useful in predicting those variables.[3]

As a matter of fact, in practice, monetary authorities do use monetary aggregates as nominal anchor to target the ultimate policy goals because of its attractive features. First, for the monetary aggregates, the narrower the measurement of money is the better because it can be controlled both quickly and easily by the central bank. It enables a central bank to adjust its monetary policy to cope with domestic considerations.

Second, because of monetary aggregates can be measured quite accurately with short lags (in the case of Malaysia, for example, measures of monetary aggregate appear within one month, BNM, 1999), information on

---

[1] BNM, nevertheless, still monitors very closely monetary aggregates, credit growth and other economic and monetary indicators.
[2] Korea, for examples, have explicitly announces an annual inflation target. Singapore, on the other hand, adopting exchange rate targeting.
[3] See Svensson (1999), and Amato and Laubach (2000), for recent discussions on the role of forecasting in monetary policy.

whether the central bank is achieving its target is known almost immediately – announced figures for monetary aggregates are typically reported periodically with very short time lags.

Third, as pointed out in Bernanke and Mishkin (1992), since monetary aggregates are known to the public, using it as a nominal anchor greatly increases the transparency of monetary policy, which can have importance benefits. A monetary target can send almost immediate signals to both the public and markets about the stance of monetary policy and the intentions of the policy makers to keep inflation check. This signal can then help fix inflation expectations and produce less inflation. In addition, the transparency of monetary aggregate targets makes the central bank more accountable to the public to keep inflation low, which can help reduce pressures on the central bank to pursue expansionary monetary policy.

In all of its potential policy role, as stresses by Mishkin (1999), in practice these advantages holds depend crucially on two big *ifs*: 'the biggest if is that there must be a strong and reliable relationships between the goal variable (inflation or nominal income) and the targeted aggregate. If there is velocity instability, so that the relationship between the monetary aggregate and the goal variables is weak, the monetary aggregate targeting will not work.'[4]

Not surprisingly, the existence of a stable long-run relationship linking money to income has been extensively investigated, as it would provide support for money targeting as a policy strategy for monetary authorities. As far as the literature are concerns, there was no conclusive evidence has emerged. While early empirical studies seemed to suggest that a log-linear equation of this kind exhibit stable long run relation (for instances, Friedman and Kuttner, 1992; Feldstein and Stock, 1994), subsequently it became apparent that the relationship had broken down. Yet, the predominant, if not universal, conclusion on the cumulative evidence in favor of long run money-income relationship is not overwhelming (for instances McDougall, 1994; Davis and Tanner, 1997): that the evidence varies with sample periods, methodology, data frequency and different money measures.

The lack of cointegration has been widely undermining the generally well-accepted stable relationship between prior changes in money and income. This weak relationship implies that hitting the target will not produce the desired outcome on the goal variable and thus the monetary aggregate will no longer provide an adequate signal about the stance of monetary policy. Nevertheless, the claim that a stable money-income long run relationship exists has resurfaced in some recent studies. Several attempts in the recent literature have tried to resolve these issues: it has been argued that cointegration can be achieved by adding other variables, such as wealth, financial innovation variables or cumulated interest rates, to a standard money demand function (see, e.g., Hall *et al*. 1990, Hendry and Ericsson, 1991, 1993). This is because velocity is highly trended, and only by including a similar effect that it is possible to build a well-balanced equation.

Alternatively, there are some studies that have looked at the various measurement of monetary aggregate to address the money-income cointegration issue (for the Asian economies, see Habibullah, 1999). This new approach to monetary aggregation was advocated by Barnett (1980) and has led to the construction of monetary aggregates based on Diewert's (1976) class of superlative quantity index number. The Divisia aggregates (also known as monetary services indexes) proposed by Barnett (1980) have been found to be superior to its counterpart the conventional simple-sum aggregate.

Using a comprehensive set of Malaysia's monetary series containing simple-sum and divisia aggregates, the main aim of this study is to examining the long run money-income relationship in Malaysia using two different approaches. To this end, the widely used Johansen cointegration test and the new Bierens' (1997) cointegration test are adopted. The rationale of adopting the nonparametric approach is simply because of its' potential superiority at detecting cointegration when the error correction mechanism is nonlinear. There is a possibility that failure to identify such a long run equilibrium in previous studies simply reflects the adoption of a standard cointegration framework, which assume a constant speed of adjustment.

Also, unlike many standard cointegration tests that are based on a parametric model, the nonparametric test is robust against misspecification and structural break in the short run component and can be used to test a wide range of nonlinear models (Breitung, 2002). On the whole, the empirical results of the present study suggest that although the long run money-income receives limited empirical support from the Johansen method, the evidence from the Bierens approach is overwhelming.

The remainder of the rest of this paper is organized as follows. Section II discusses the econometrics method adopted. The data description and the construction of divisia money are briefly discussed in Section III. This follows by the estimates results reported in Section IV. Lastly, concluding remarks are offered in Sections IV.

---

[4] The second if is the degree to which the intermediate target is controlled by monetary authority.

TESTING FOR COINTEGRATION

A substantial part of the economic theory deals with long run equilibrium relationships generated by market forces and behavioral rules. The theoretical relationship between money and income has been a popular topic in the economic research. Monetarists relied on the equation of exchange as a theoretical framework for explaining the relationship between money and income. In this setting, from the identity, MV = PY, where M is the nominal supply, V the velocity of circulation and PY is the nominal income, in accord to monetarist analysis, for long periods, there exist a consistent and precise money-nominal income relationships, since movements in velocity are usually small. And given that the volume of output is determined by real factors, the aggregate price level is mainly influenced by the stock of money.

A key issues here is that whether there existence such relationship, which linked monetary aggregates and nominal income in the long run. If there is no such evidence, then, there is no empirical support for assigning any role in monetary policy to a monetary aggregate. As mentioned earlier, methodologically, there are two different statistical approaches involved in testing the existence of long run money-income relationship in the present study. On one hand, is the standard cointegration procedure, that is, the Johansen (1988, 1991). On the other hand, given that the true Data Generating Process (DGP) of economic time series is generally unknown to the analyst, it might be useful to employ alternative testing procedure, as a consistency cointegration test (Bierens, 1997c). This motivated the use of the recent proposed nonparametric cointegration test suggested by Bierens (1997c).

The Johansen (1988, 1991) Cointegration Test

Johansen suggest a test for determining the number of cointegrating vector among a group of variables based on the vector autoregressive (VAR) system of n x 1 vector of X_t variables.

$$\Delta X_t = \mu + \sum_{i=1}^{k-1} \Gamma_1 \Delta X_{t-1} + \Pi X_{t-k} + \varepsilon_t \tag{1}$$

where $\Gamma_j = -\left(I - \sum_{i=1}^{j} \phi_i\right)$, $\Pi = -\left(I - \sum_{i=1}^{k} \phi_i\right)$, μ is the constant term, I is the identity matrix and the

disturbance vector ε_t of dimension (p x 1) is distributed as an i.i.d. Gaussian process with zero mean and variance Ω (see Johansen (1991) for details). The long run relationships in the data set are determined by the rank of Π. If the series are nonstationary and cointegrated, the Π is not a full rank, but 0 < rank (Π) = r < p, where r is the number of cointegrating vectors. Johansen proposes two likelihood-testing procedures in order to test for the null of no cointegration. The first test is that the number of cointegrating vectors is, at most, equal to r (trace test). The second test of the hypothesis that the number of cointegrating vectors is equal to r (max Eigenvalue test). These statistics are compute as follow:

$$\text{trace} = T \sum_{i=r+1}^{N} In(1-\lambda_i) \text{, and}$$

$$\text{Max-L} = T \ln(1-\lambda_{r+1}) \tag{2}$$

Where r is the number of distinct cointegrating vectors, and $\lambda_{1...\lambda_N}$ are the p squared canonical correlations between the X_{t-p} and Δx_t series.

The Bierens (1997) Cointegration Test

As in most of the cointegration approaches in the literature, the Johansen (1988, 1991) test requires consistent estimation of nuisance and/ or structural parameters. Bierens (1997c) propose consistent cointegration, which do not need specification of the data-generating process, apart from some mild regularity conditions, or estimation of (nuisance) parameters. Such an approach is called 'model free' in Bierens (1997a) and 'nonparametric' in Bierens (1997c). The Bierens cointegration test is conducted analogously to Johansen and Jeselius test: the test statistic involved is obtained from the solutions of a generalized eigenvalue problem, as well as the inclusive of the test for parameter restrictions on the cointegrating vector. However, unlike the Johansen test, Bierens

nonparametric approach has some clear advances, in particular that it does not require specifying a lag length and the deterministic variables of the ECM term, and the critical values are case independent (Bierens, 1997b)[5].

In the same spirit as Johansen's lambda–max test, Bierens considered the lambda-min statistics, $\hat{\lambda}_{n-r_0,m}$, for testing the hypothesis of:

$$H_0(r_0): f = r_0; \qquad H_1(r_0): r = r_0 + 1$$

The Bierens' cointegrating test is based on the generalized eigenvalues of matrices A_m and $(B_m + T^{-2} A_m^{-1})$, where

$$A_m = \frac{8\pi^2}{n} \sum_{k=1}^{m} k^2 \left(\frac{1}{n} \sum_{t=1}^{n} \cos(2k\pi(t-0.5)/n) z_t \right) \times \left(\frac{1}{n} \sum \cos(2k\pi(t-0.5)/n) z_t \right)'$$

$$B_m = 2n \sum_{k=1}^{m} \left(\frac{1}{n} \sum_{t=1}^{n} \cos(2k\pi(t-0.5)/n) \Delta z_t \right) \times \left(\frac{1}{n} \sum_{t=1}^{n} \cos(2k\pi(t-0.5)/n) \Delta z_t \right)' \qquad (3)$$

Which based on weighted means of z_t and Δz_t.

Rather than testing for the number of cointegrating vectors, r, Bierens also provides the $\hat{g}_m(r_0)$ for estimate it consistently, calculated from the generalized eigenvalues:

$$\hat{g}_m(r) = \left(\prod_{k=1}^{q} \hat{\lambda}_{k,m} \right)^{-1} \qquad \text{if r = 0,}$$

$$= \left(\prod_{k=1}^{q-r} \hat{\lambda}_{k,m} \right)^{-1} \left(n^{2r} \prod_{k=q-r+1}^{q} \hat{\lambda}_{k,m} \right) \qquad \text{if r = 1,…, q-1}$$

$$= n^{2q} \prod_{k=1}^{q} \hat{\lambda}_{k,m} \qquad \text{if r = q,} \qquad (4)$$

When the series are found to be cointegrated, Bierens further demonstrated that one could deploy test for linear restriction on the cointegrating vector on the basis of the ordered solutions of the eigenvalue problems as follows:

$$\det[H^T A_m H - \lambda H^T (A_m + T^{-2} A_m^{-1})^{-1} H] = 0 \qquad (5)$$

where H is the hypothesized restricted matrix. The critical values of trace (m = 2q, $F_k(x) = \cos(2k\pi)$) and lambda-max (m = 2q, $F_k(x) = \cos(2k\pi)$) statistics are given in Bierens (1997c, Tables 3 and 4).

DATA DESCRIPTIONS AND THE CONSTRUCTION OF DIVISIA AGGREGATES

To detect the existence of long run relationship between income and money, the Johansen (1988, 1991) and Bieren nonparametric tests are applied on the simple sum M1, M2 and the divisia money M1, M2 originally calculated by Habibullah (1999). As for nominal income, since GDP is only available annually, quarterly data are interpolated from annual observation using Gandolfo (1981) technique. The quarterly time-period considered in this study spanning from 1981:1-1994:4.

The monetary aggregates currently in use by the BNM (and many central banks over the world) are based on simple-sum method of aggregates. The essential property of this method of monetary aggregates is it was calculated on the assumption that their relative prices are constant and receive equal (unitary) weight. Despite of its simplicity, empirical evidence demonstrated by Fleissig and Serletis (1999) indicated that such assumption is unrealistic.

---

[5] Caporale *et al.* (1997) argue that the Johansen test procedure is crucially affected by the correct specification of the VAR and show that where an adequate VAR can be achieved the assumption of cointegration is no longer supported.

The Divisia aggregate proposed by Barnett (1980) are based on the so-called superlative class of quantity index numbers.

$$G(Q_t) = \sum_{i=1}^{n} s_{it}^* G(q_{it}) \tag{6}$$

Equation (6) defines the growth rate of a divisia aggregate as the share-weighted average of the growth rates of the component asset quantities. $s_{it}^* = 0.5(s_{it} + S_{i,t-1})$ is the average of expenditure shares from the two adjacent periods and the expenditure share on the services of monetary asset i in period t is measures as

$$s_{it} = p_{it} q_{it} / \sum_j p_{jt} q_{jt} . \tag{7}$$

Where q_{it} and p_{it} respectively, represent the quantities and the user cost of each asset to be included in the aggregate at time t.

The user cost of each asset as derived in Barnett (1978), measures the opportunity cost of the monetary services provided by asset i for the given period is:

$$p_{it} = (R_t - r_{i,j})/(1 + R_t) \tag{8}$$

where R_t is the benchmark rate, the maximum $[r_j, r_i; 1 = 1,2,...,n), j = 1,2,...,k, i \neq k]$. (See Habibullah (1998, 1999) for more detail regarding the divisia approach to monetary aggregate used in the present study).

ESTIMATED RESULTS

Methodologically, the issue of unit root in time series is examined from different perspectives – from the unit root null as well as from the stationary null. In this regard, two non-parametric methods are applied, namely the Phillips-Perron (PP) test (1988) and the Bierens and Guo (1993) Cauchy test #3 are employed in this study. To mitigate possible finite-sample bias in the PP test, appropriate finite-sample p-values are simulated on the basis of 1000 replications of a Gaussian AR(1) process. The PP test employs a Newey-West type variance estimator of the long run variance of the OLS auxiliary regression, with the trancation lag $m = cn^r$, where $c = 5$, $r = 0.25$, n = number of observations.

Evidently, from Table 1, the results revels that simple-sum, divisia money and income can be modeled as I(1) processes. In such a case, the analysis proceed to test whether the monetary aggregates is pair-wise cointegrated with income. Table 2 presents the results of Johansen cointegration test. The order of the VAR model is chosen based on the Schwarz criteria. Among the four different money measures, both the maximum eigenvalue and trace statistics suggest that there is long run relationship exists between nominal income and Divisia M1.

To ensure that the results of Johansen approach are robust to the data-generating process, the Bieren's (1997c) nonparametric cointegrated test is adopted. As reported in Table 3, the lambda min and the $g_m(r_0)$ detected that long run relationship exists between the nominal income and the four types of money measurements and the cointegrating null $[1 -1]$ cannot be rejected.

Table 3: Bierens Cointegration Test Results

	Hypothesis	λ min	Hypothesis	$g_m(r_0)$	H_0: $\beta' = (1\text{ -}1)$[2]
SM1	$r = 0$	0.0087*	$r_0=0$	4.85E+02	(1 -0.9153)
	$r = 1$	0.4266	$r_0=1$	**3.43E+01**[3]	1.02
			$r_0=2$	1.89E+04

	$r = 1$	0.1003	$r_0=1$	**3.28E+01**	1.21
			$r_0=2$	9.99E+02	

[1] Lambda-min test statistic; m are chosen based on the optimal values tabulated in Bierens (1997c).

[2] Trace test for linear resections, m = 2n with the n the dimension of the system.

[3] Estimated number of cointegrating vectors is: $\hat{r} = \arg\min_{r0 \leq 2} g_m(r_0), m = 2$. Bold indicates minimum value of statistic.

In principle, the Bierens method is in the same spirit with the Johansen procedure. Based on the Monte Carlo simulations using a linear ECM, Bierens demonstrated that similar results can be obtained from both procedures. The failure of Johansen cointegration test in detecting the long run equilibrium relationship between the money and income reflect the inability of the standard linear cointegration framework in capturing the nonlinearity of the adjustment process, which assume to be constant over time.

CONCLUSION

The recent studies have questioned the policy role of monetary aggregates. A key issue is that whether there remain any significant evidence of stable long run relationship linking monetary aggregate and the nominal economic activity. This study is an attempt to detect the presence of long run money-income relationship using two different approaches, which are the parametric and nonparametric procedures. To this end, the widely-use Johansen (1988, 1991) cointegration test and the Bierens (1997c) nonparametric cointegration tests are employed. All cointegration analysis are tested between four aggregate definitions – simple-sum M1, M2 and divisia M1 and M2 with the nominal income.

Evidently, the empirical results indicated that there exists long run relationship between money (various defined) and income. In particularly, while the standard Johansen Cointegration test reveals that most of the monetary aggregate measures are not cointegrated with the nominal income, clear evidence of long run cointegration are offered by the Bierens nonparametric approach, which contrast sharply with a number of existing evidence obtained from standard cointegration tests. The empirical findings suggest that the potential policy role of monetary aggregate cannot be ruled out.

Indeed, as Breitung (2002) pointed out, under certain situations, the nonparametric approach may be attractive. The nonparametric test is robust against deviations from the usual assumption of linear short run dynamics, since the short run component does not affect the asymptotic null distribution of the test statistic. Also, if a high augmented lag is needed or the results depend sensitively on the number of lags included in the regression, it may useful to apply nonparametric tests.

Financial Development and Economic Growth:
Evidence from Malaysia

ABSTRACT

This study attempts to examine the relationship between economic growth and the growth of financial development in Malaysia for the period of 1970-2003 by using Engle-Granger Procedure and Granger Causality Test. The empirical results suggested that a long-run relationship exist for economic growth and financial growth. A unidirectional causality from economic growth to the growth of financial development is found. This implies that the past information of financial development could not be used to predict the future movement of real economic growth.

_____

INTRODUCTION

The role of financial sector development in the growth process has received considerable attention in the economic literature in the last few decades. Numerous studies have attempted to establish the relationship between financial development and growth and the channels of transmission through which financial sector affects economic growth. Many economists hold the view that financial development is crucial in achieving a higher rate of economic growth. The general idea was that financial development might affect economic growth through its main functions of mobilizing domestic savings and allocation of capital. Since a developed financial system implies that the transaction, information and monitoring costs are reduced, it should therefore efficiently allocate resources - savings to productive economic activity and also increase capital formation, which in turn induces growth. In other words, a country with a better-developed financial system grows faster than those countries with less developed financial system.

It is evidence that more developed countries have more developed financial markets whereas in developing economies the financial system is among the most heavily regulated sectors of the economy. Government restrictions on the banking system like the imposition of interest rate ceilings, directed allocation of credits and control on the inflows of foreign capital (financial repression) hinder financial development and thus reduce growth rate. However, in the past decade there has been a dramatic reform of financial sectors in many developing countries. It is believed that liberalization and policies to develop the financial sector would be expected to stimulate economic growth.

Financial development means an improvement in quantity, quality, and efficiency of financial intermediary services (Lin Liu, 2003)[1]. An efficient system of payment is necessary condition for growth as it reduced transaction and information costs. The existence of an efficient intermediation system leads to a better mobilization of available savings and efficient allocation of resources to higher return investment opportunities by making the agglomeration of existing financial resources in the economy easier. Financial intermediaries can provide savers with higher return investments and also enables them to diversify risks associated with those investments. Reorientation of savings from real assets investment with low returns to high-expected return financial assets and to productive investments may encourage capital formation and hence stimulate growth. Therefore, services provided by financial intermediaries could have positive net effect on the economy's long run growth rate and this theoretical relationship between financial development and growth has been recently analyzed using endogenous growth model.

Based on the paramount importance of financial development for economic growth, many empirical researches were undertaken to investigate the relationship as well as the issue of causality either at firm, industry, country-case or cross-country level. The conclusions reached suggest that financial intermediation has a positive effect on economic

_____

[1] Broadly defined, financial development includes financial intermediary development and stock market development.

growth. However, the direction of causation is unclear. In some cases, the causality is found to be one way, some bi-directional, while in some other cases the relationship reflects reverse causality. Evidence on causality is important for policymakers because it has different implication for development policy whether policies should be aimed to financial sector liberalization or to enhance growth (Calderon & Liu, 2003).

Before the onset of 1997 financial crises in the Southeast Asia, Malaysia has achieved a remarkable economic growth for many decades. Its GNP per capita rose from only $390 in 1970 to $4 370 in 1996 as a result of higher growth rates. Along with this rapid growth, the financial sector has experienced rapid structural transformation too. Despite of its spectacular growth performance, Malaysia was badly hit from the financial crisis and this further underline the importance of a well-functioning financial sector to the economy. With regards to this scenario, one pertinent question might be raised: is there any link between financial system and the macroeconomic performance of an economy, and if any how does financial sector affect economic growth? In view of this, the paper attempts to analyze whether there is any evidence for financial development promotes economic growth of the Malaysian economy or vice versa. Following the introduction, part 2 briefly reviews some of the existing literature on financial development and economic growth. Part 3 discuss the methodology and the data used, and the empirical results will be discussed in part 4. Part 5 provides a summary and concluding remark.

THEORETICAL AND EMPIRICAL LITERATURE

The theoretical and empirical literature on the relationship between financial development and economic growth has grown extensively ever since the writings of Schumpeter (1912), Patrick (1966), and more recently McKinnon (1973), Shaw (1973), and King and Levine (1993) among others. Theoretically, the proposition is that development of the financial system is an important input for achieving and sustaining economic growth. Schumpeter argues that services provided by financial intermediary encourage technological innovation by identifying and funding entrepreneurs to foster economic development. McKinnon and Shaw contend that financial development affects economic growth through interest rate. Higher real interest rate resulting from financial liberalization would raise savings and will lead to increased investment and economic growth. He argued that government intervention on the development of the financial system such as interest rate ceilings would discourage savings, which then reduce the availability of loanable funds for investment. This in turn will lower the rate of economic growth.

Patrick (1966) viewed the role of financial development to economic growth as 'supply-leading and demand-following'. The 'supply-leading' role of financial development views postulates that financial sector leads to economic growth in such a way that the existence of financial intermediaries and markets increases the supply of financial services, and hence economic growth. The 'demand-following' views posit that development of the financial sector is facilitated by growth in the real sector. The need for financial services and institutions arise as the economy grows. He also recognized a two-way relationship, which depends on the stage of economic development. In the early stages of development, financial sector development is consistent with the 'supply-leading' view and during the advanced stages of development it is consistent with the 'demand-following' view. Levine (1997 : 689) explained the role of financial system in economic growth based on functional approach that focus on the ties between growth and the quality of the functions provided by the financial system. He categorizes the functions of financial system into five basic tasks – facilitate trading, hedging, diversifying, and pooling risk; allocate resources; monitor managers and exert corporate control; mobilize savings; and facilitate the exchange of goods and services. He suggests a positive first order relationship between financial development and economic growth.

Some economists demonstrate theoretical discussions on the potential role of financial sector development on economic growth within the framework of endogenous growth model. These include studies by Bencivenca and Smith (1991), Greenwood and Jovanovic (1990), King and Levine (1993), and De Gregorio and Guidotti (1995). According to Bencivenca and Smith (1991), individuals are uncertain about their future liquidity needs, and they choose to invest in liquid assets with low productivity and forgoing the riskier assets with high productivity but illiquid. With the presence of financial intermediaries savings is channeled to high productive investment and at the same time reduce the risk associated with their liquidity needs. Hence, growth will be increased. Greenwood and Jovanovic (1990) examines the relation between financial structure and economic development and found that there exists a positive effect of financial structure on growth. The reason for this is that financial intermediation allows efficient investment undertakings with higher returns and capital accumulation as a result of information about the nature of shocks on investments. King and Levine (1993) employ an endogenous growth model in which the financial intermediaries obtain information about the quality of individual projects that is not readily available to private

investors and public markets. This information advantage enables financial intermediaries to fund innovative products and productive processes, thereby inducing economic growth.

On the empirical side, a number of recent studies have tried to assess the importance of financial development to economic growth. Some of the studies try to identify how does financial sector affects economic growth; where as other studies investigate the correlation and evaluate the strength of the relationship between financial development and economic growth. Several measures or indicators for the development of the financial system have been constructed to examine the channels through which financial development is linked to economic growth. However, the diversifying services provided as well as various agents and institutions involved in financial intermediation activities make it difficult to have good measures of financial development.

One of the most influential empirical studies is by King and Levine (1993) who employs endogenous growth model that covers a cross section data of 80 countries over the period of 1960-1989. They found a strong positive link between financial development and growth. In a more recent study, Levine (1997) suggests a positive, first-order relationship between financial development and economic growth. Four measures of the level of financial development are considered which are liquid liabilities of banks and non-bank institutions as a share of GDP, the ratio of bank credit to the sum of bank and central bank credit, the ratio of private credit to domestic credit, and the ratio of private credit to GDP. In addition, King and Levine study also shows that financial development is robustly correlated with rate of growth, capital accumulation and economic efficiency, indicating a causal relationship from financial sector development to economic growth.

The direction of causation between the level of financial development and economic growth was also empirically examined and reported by Jung (1986), Demetriades and Hussein (1996), Rajan & Zingales (1998), and Calderon and Liu (2003) among others. The evidence suggests a two-way relationship, one-way relationship as well as reverse causality. Using post-war data for 56 selected countries; Jung (1986) used two proxies to financial development, which are the ratio of currency to M1 and the ratio of M2 to nominal GDP. He found bi-directional causality between financial and real variable, indicating a causal direction from financial to real sector for the developing countries but for developed countries the causality runs from real sector to financial sector. Rajan & Zingales (1998) present industry level evidence that link financial development and economic growth through the supply of external finance to firms. They found that industrial sectors that are relatively more in need of external finance grow faster in countries with more developed intermediaries and stock markets than in countries with less developed financial markets. The result also shows that financial development lowers the cost of external financing and therefore induces economic growth, suggesting causality from financial development to economic growth.

Calderon and Liu (2003) employs Geweke decomposition test on pooled data of 109 countries to explore the direction of causality between financial development and economic growth. The study shows evidence that financial development enhances economic growth and the existence of bi-directional causality. Evidence from study conducted by Demetriades & Hussein (1996) for 16 countries provides less support on the role of financial sector in the process of economic development. They found that the causality pattern varied across countries. The same result was also found in De Gregorio and Guidotti (1995) and Sinha & Macri (2001). On the contrary, a conclusion reached by Ram (1999) based on individual-country analysis does not support the view that financial development promotes economic growth, and further, estimates from basic multiple regression growth model also do not indicate a positive association between financial development and growth. In a country-case study, better functioning financial systems support faster growth. This result was also found by Khan and Senhadji (2000), and Fase and Abma (2003).

METHODOLOGY AND DATA

This paper considers individual country regression analysis rather than cross-country estimates. The Engle-Granger Procedure and Granger Causality methods are used to study the relationship between economic growth (real gross domestic product, RGDP) and financial development growth (FD). Before any causality test can be performed, the integration orders of time series should be verified. This is because the test procedure requires that the time series used for causality should be stationary. The first step is to pretest the variables (RGDP and FD) for their order of integration by differencing each series successively until a stationary series is obtained. The tests for this are the Augmented Dickey Fuller (ADF) unit root test:

$$\Delta RGDP = \mu + \gamma RGDP_{t-1} + \delta_1 \Delta RGDP_{t-1} + \delta_2 \Delta RGDP_{t-2} + \ldots + \delta_p \Delta RGDP_{t-p} + E_t \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots(1)$$

If the results of step 1 indicate that each pair of series is integrated at the same order, the next step is to estimate the long run equilibrium relationship in the form:

$$RGDP_t = \beta o + \lambda FD_t + E_t \dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots(2)$$

In order to determine which pair of series is actually cointegrated (or have long run relationship), denote the residual sequence (i.e. L) from equation (2). Thus, {L} is the series of the estimated residuals of the long run relationship. If these deviations from long run equilibrium are found to be stationary, the RGDP and FD sequences are co integrated. A Dickey-Fuller test can be performed on these residuals to determine their order of integration. Consider the auto regression of the residuals below:

$$\Delta L_t = \Phi^* L_{t-1} + \mu_t \dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots.\dots\dots\dots\dots(3)$$

Since the {L} sequence is a residual from a regression equation, there is no need to include either an intercept term or a trend in its augmented version. The reason to apply this is because the expected value of the series is equal to zero (since they are the error terms), and the intercept is also equal to zero.

The third step is estimating the Error-Correction Model (ECM). The ECM developed by Engle-Granger is a means of reconciling the short run behaviour of an economic variable with the long run behaviour (Gujarati, 1995). In other words, this model tries to determine the size and direction of the adjustment of the cointegrated variable(s) that returns to the long run equilibrium relationship after a temporary movement away from it. If the two variables are cointegrated, one can establish their relationship with an ECM by the two-stage process. In the first stage, the long run parameters are estimated. This is achieved simply by estimating the cointegrating regression:

$$RGDP = \beta o + \beta_1 FD_t + \mu_t \dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots...(4)$$

This can be done by OLS (ordinary least square) regression. β_1 is called the cointegrating coefficient. It shows how much and in what direction the growth of financial development needs to move in order to the influence of the growth of real GDP.

In the second stage, the short run relationship is investigated by estimating the following equation using the error term, e_t from equation (4).

$$\Delta RGDP = \sum_{i=1}^{n} \delta i \Delta RGDP_{t-i} + \sum_{i=1}^{m} \gamma j \Delta FDt\text{-}j - \lambda_1 e_{t-1} + \varepsilon_t \dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots(5)$$

and

$$\Delta FD = \sum_{i=1}^{n} \delta i \Delta RGDP_{t-i} + \sum_{i=1}^{m} \gamma j \Delta FDt\text{-}j - \lambda_2 e_{t-1} + \varepsilon_t \dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots.(6)$$

RGDPt and FD are the natural logarithms of real GDP and financial development. n and m are the number of lags and e_{t-1} is the lagged value of the error-correction, which is derived from the cointegrating equation in the first stage. In testing these equations, the error correction term must be included to avoid misspecification. The omission of one lag at the error-correction term (ECT) is necessary because the effects of additional lagged ECTs are already captured in the distributed lags of the first differences of RGDPt, and FDt (Engle and Granger, 1987). Parameters λi are called the speed of adjustment coefficient. For instance, parameter λ_2 corresponds to the speed of adjustment of FD to the long run equilibrium in the next period after a temporary deviation from it in the current period (Carlos, 1997).

It should be noted that the precise lags (n,m) on the differenced terms in the above equation are not specified by Granger Representation Theorem. A possible approach to determine the optimal lags is to use the Akaike Information Criterion (AIC). The optimal lags are chose base on the minimum value of AIC. Finally, the optimal lags from the ECM are fitted into the Granger Causality equations.

DATA

This study uses secondary data, consisting of annual data for Real Gross Domestic Product, RGDP; and financial development, FD. Each of the data is transformed into the logaritma form before proceeding any tests.The study period spans from 1970 to 2003. The data is obtained from International Financial Statistic CD-ROM. Real Gross Domestic Product is used as proxies for economic growth. For financial development measure, we followed the previous studies (Gregorio & Guidotti (1995) and Sinha & Macri, (2001)) one. In existing literature, many proxy variables have been used to represent financial development such as (i) the ratio of monetary agregates (M1, M2 and M30 to GDP; (ii) the ratio of domestic credit to the private sector to GDP; (iii) the ratio of liquid liabilities to GDP. In this study, we choose the ratio of domestic credit to the private sector to GDP as a proxy of financial development. The ratio of monetary agreggates to GDP is not been chosen because according to Khan & Senhadji (2000), M1, M2 or M3 are poor proxies for financial development. They are more related to the ability of the financial system to provide transaction services than to the ability to channel funds from savers to borrowers. By excluding credit to the public sector, the ratio of domestic credit to the private sector to GDP measures more accurately the role of financial intermediaries in channeling funds to the private sector. However, private credit is only a broader measure of banking sector development whereas the definition of the financial development should be included the development in money market and capital market. We have to exclude the capital market data because of unavailability of complete data.

ANALYSIS OF EMPIRICAL RESULTS

Table 1 shows the augmented Dickey-Fuller unit root tests results. For the level of the series, none rejects the hypothesis of nonstationarity at 5 per cent significance level. After the first differencing, we are able to reject the null hypothesis of a unit root at 5 per cent significance level.

Table 1: Unit Root Tests Results

Variables	Constant Without Trend	Constant With Trend
	Level	
RGDP	-1.2049(2)	-2.2359(1)
FD	-1.7070(1)	-2.0389(1)
	First Difference	
RGDP	-4.0656(1)*	-4.1905(1) *
FD	-3.9583(1) *	-4.1223(1) *

Note: RGDP is real GDP and FD refers as financial development. The critical values for rejection of the ADF tests are –2.93 and –3.50 at a significance level of 5%, where a constant without trend and a constant with a time trend are included in the equation. The asterisks (*) indicate the level of significance at a 5%. The number in each parenthesis indicates the optimal lag length used in the test. The optimal lag length is determined based on Akaike Information Criterion (AIC).

Table 2: Empirical Results of Cointegration Test

Residual	Dickey-Fuller Test
RGDP & FD	-1.9810 (0)*

Note: The asterisk denotes significance at the 0.05 level where the critical value is –1.95.

Table 2 presents the result of cointegration analysis for RGDP & FD. The residual sequence for RGDP & FD is stationary at 5% significance level. This means economic growth and financial development have long run relationship. In other words, we say the series is cointegrated.

The two-stage procedure is quite straightforward. First the long-run effects are estimated as below:

$$\hat{RGDP} = 4.2725 + 1.0821 \, FD \quad\dotfill(7)$$
$$(110.3147) \quad (21.5709)^*$$

Note: Equation (7) represents the long-run effect for real GDP and financial development (FD). The values in the parenthesis are the t-statistics. The asterisk (*) denotes significant at the 0.05 per cent level of significance.

From the regression above, the signs on the estimated coefficient indicates positive correlation between the economic growth (real GDP) and the growth of financial development (FD) in the long run. This correlation may not reflect a causal relationship between real GDP and FD. It means while other things being equal, 1 per cent change in the growth of financial development will cause economic growth to increase to 1.0821 per cent.
Table 3 reports the optimal lags for error-correction models. The lags range from 1 to 3.

Table 3: Error Correction Model

Regression	Dependent Variable	Speed of Adjustment Coefficients	n,m	AIC
RGDP & FD	RGDP	0.0004 (0.9927)	3,1	-3.3402
	FD	0.2037 (0.0770)*	1,1	-1.7954

Note: The number in each parenthesis indicates the p-value of each adjustment coefficient. The asterisk denotes significant at 0.10 per cent level.

The important information we take from the error correction model is the speed of adjustment parameters. From table 3, we observe that in the short run just one of these parameters is significant. It means that after a disequilibrium between two variables, (namely economic growth (Real GDP) and growth of financial development (FD)) just the growth financial development converges again to the long run equilibrium. The value of this coefficient is 0.2037 which means that 20.37 per cent of the adjustment is done within the first year after the disequilibrium.

Finally, table 4 presents the F-statistics for the tests of the causal link between Real GDP and FD. Based on this empirical result, we can conclude that a unidirectional causality from real GDP to FD is found. Real GDP leads FD by one year. This means FD can be predicted with better accuracy by using past values of real GDP, with the assumption that other information being identical.

Table 4: Granger Causality Test Results

Hypothesis	F-value	p-value	Decision ($\alpha = .05$)	Direction of causality
RGDP & FD				
FD→RGDP	0.71435	0.40469	Do not reject Ho	No causality
RGDP→FD	5.20033	0.02986	Reject Ho	Unidirectional causality

It is clear that the growth of financial development does not predict the economic growth for Malaysia case. The conclusion is not consistent with Choong, et. al (2003) and Romer (1990), but the significance and positive relationship between real GDP and financial development result is similar as Sinha and Macri (2001). The empirical results that obtained from this study also support the growth-led finance hypothesis that state a high economic growth may create demand for certain financial instruments and arrangements and the financial markets are effectively response to these demands and changes.

DISCUSSION AND CONCLUSION

Obviously, the financial development could not be the information provider for the subsequent movement in economic growth. It may indicate that financial development is not a leading indicator. This may be due to the following reasons. Malaysia is a small country and its economy has been very open since independence. Hence, other forces such as oil prices, world economic and political conditions are much more influential and have significant impact on Malaysian economic growth than financial development. This implies that the financial development data may not predict the future movement of economic growth especially in the open yet small country such as Malaysia significantly.

Meanwhile, the financial development in Malaysia remains at the emerging level if we compared with developed countries. For the past decades, the main financial development has been focused on banking sector rather than capital market. Until 1990s then only more attention has been devote on the development of capital market and restructuring the banking system. The less developed capital market and solid banking system may cause financial development data no longer a good predictor for Malaysian economic growth. Besides, the lag effect of financial impact may cause it failed to be a good predictor for future movement of economic growth.

Other factors such as the type and time period of data and methodology used in this study may also reduce the potential usefulness of financial development as information provider for future movement of economic growth. For example financial development should consist the data of three areas, namely banking and non-banking sector, stock and bond market. Yet, the data used as the proxy for financial development in this study comprised only the domestic credit data. It has excluded the data of stock capitalization and bond market because of unavailability of such data for the sufficient study period. The usage of this narrow definition or scope of financial development may lead to the failure of financial development as a precise predictor for economic growth.

The empirical finding of the study indicates that the past information on financial development failed to predict the future movement of economic growth. This would suggest that to increase the ability and reliability of financial development data, much effort should be done on consolidating every aspect of both money and capital markets in Malaysia. These include develop the indicators that able to assess the development of financial sector in Malaysia (such as bank quality service index and the efficiency of capital market) and improve the current financial statistics data. If necessary, the innovation in financial sector should be taken into account while developing the new indicators or improve the current statistics data.

If financial development data failed to be the predictor for economic growth, then the Central Bank should monitor closely the movement of the international sectors' to reduce the contagion effect that will eventually affect our economic growth and economic forecasting. To enhance the reliability of financial data, sound financial practices and market should be created by Central Bank. To have sound financial market, we should not rely heavily on foreigners. In contrast, we should encourage more domestic players to participate in financial markets (either act as excess or deficit units). This can be done by educating the locals and disseminating more information throughout the country.

To conclude, this study attempts to examine the relationship between economic growth and the growth of financial development in Malaysia for the period of 1970-2003 by using Engle-Granger Procedure and Granger Causality Test. The empirical results suggested that a long-run relationship exist for economic growth and financial growth. A unidirectional causality from economic growth to the growth of financial development is found. This implies that the past information of financial development could not used to predict the future movement of real economic growth.

The relationship between economic growth and the growth of financial development is a long lasting research topic. There are on going efforts, both theoretical and empirical, to investigate the controversy of thought among the economists. It would be interesting if future researchers could include more factors that influence economic growth and expand the scope of study to other countries.

ASTRACT

This study aims to re-investigate the causal relationships between money and price level in Malaysia using Modified Wald (MWALD) test developed in Toda and Yamamoto (1995). Quarterly data for the period 1970:1-1998:4 were used in analysis. The results of MWALD tests reveal a uni-directional causality that is from money to price level. However, no reversed causality found from price level to money. This findings are different from Pinga and Nelson (2001) where no causality between these two variables. Furthermore, this study provides empirical evidence to support monetarist view. Finally, several policy implications have been discussed in this study.

INTRODUCTION

The relationship between money supply and aggregate prices has been a long debated, particularly the causal relationship among the variables. According to Pinga and Nelson (2001:1271), the direction of causality has long been a matter of controversy. The two theories obviously hold in this debate are first, the widely accepted Quantity Theory of Money (monetarist) argues that inflation is caused by exogenous changes in the money supply. Second, is a minority *structuralist* view, which holds that inflation, particularly in less-developing countries, develops from pressures arising in economic growth in economies with institutional rigidities (particularly in agriculture and international transactions). Thus, the monetary and fiscal authorities choose to expand the money supply, ratifying the inflationary pressures, rather than face unemployment or disruptions in consumption and investment. Underdeveloped financial markets and a weakly independent central bank can contribute to the likelihood of money supply growth. Under this view, money supply expansion is a consequence of, and therefore caused by structural inflation.
