Background: The genetic features indicate a crucial role in nephrolithiasis. The present study was aimed to investigate the role of Glutathione-S-transferase Mu (GSTM1), Glutathione-S-transferase Theta (GSTT1) and endothelial nitric oxide synthase (eNOS) gene polymorphism in nephrolithiasis. **Methods:** We involved a case-control study in which 480 individuals were divided into 240 healthy control and 240 patients with nephrolithiasis. For each patient and control, we measured biochemical criteria, levels of glutathione S-transferase, eNOS, GSTM1, GSTT1 genes and eNOS genes polymorphism by PCR-RFLP. **Results:** GSTM1 and GSTT1 null genotypes are not a risk features for nephrolithiasis. The eNOS frequency GG, GT, and TT genotypes by using Ban II enzyme as restriction enzyme were found to be (48.33, 36.67, and 15.00)%. The eNOS frequency TT, GT, and GG genotypes by using the Ban II enzyme as restriction enzyme were found to be 15.84, 25.83, and 58.33%, respectively. The result showed an increase in serum eNOS levels were in the patient's group comparing to control. **Conclusions:** This work is the first in the literature to study the relation between eNOS genes polymorphisms and nephrolithiasis. The results conclude that TT genotypes in the eNOS genes are associated with an increase the oxidative stress in patients. © 2019 Elsevier B.V.
