Editor: Dr. Mohamad Shafiq Mohd Ibrahim

Aims and Scope:

International Journal of Orofacial and Health Sciences (IJOHS) is a peer reviewed biannual international journal dedicated to publish high quality of scientific research in the field of orofacial sciences, health sciences and interdisciplinary fields, including basic, applied and clinical research. The journal welcomes review articles, original research, case reports and letters to the editor. Areas that are covered include but are not limited to dental sciences, oral microbiology and immunology, oral maxillofacial and craniofacial surgery and imaging, dental stem cells and regenerative medicine, dental biomaterial, oral maxillofacial genetic and craniofacial deformities.

Published by:

Abstract

Antibiotic resistance is a major global problem, associated with inadvertent drug usage. Herbal interventions are a therapeutic strategy that warrants greater research attention. Flaxseed and *Nigella sativa* are well recognized original super foods that have demonstrated potent anti-microbial and anti-biofilm activities. In the oral cavity, the bacterial population is a result of the dynamic relationship between pathogens and commensals *Streptococcus pyogenes* is an important global human Gram-positive pathogen that causes a wide variety of acute infections, it is highly virulent since it has the ability overcome the host defence system. This in vitro study aims to evaluate antimicrobial activity of flaxseed and *Nigella sativa* extract against *S. pyogenes*. Ethanolic extract of flaxseed and *Nigella sativa* extracts were prepared and the minimum inhibitory concentration (MIC) and minimum bactericidal concentration (MBC) against *S. pyogenes* was estimated. The results of this study show that both extracts exhibited antibacterial activity against *S. pyogenes*. Present study demonstrated the bactericidal activity of both extracts which can be an adjunct to the future natural anti-bacterial therapy.

Keywords: Antibacterial effect, flaxseed, *Nigella sativa*, *Streptococcus pyogenes*

Introduction

Nowadays, there is a consumer preference for natural products over synthetic drugs. One of the main reasons for the same is to avoid the adverse effects of synthetic medications and the risks of bacterial resistance (David & Gordon, 2012). In the oral cavity, the bacterial population is a result of the dynamic relationship between pathogens and commensals *Streptococcus pyogenes* may contribute to many human diseases, ranging from mild superficial skin infections to life-threatening systemic diseases. Infections typically begin in the throat or skin. Infections due to certain strains of *S. pyogenes* can be associated with the release of bacterial toxins that can lead to scarlet fever (Hammer, 2007). Other toxigenic *S. pyogenes* infections may lead to streptococcal toxic shock syndrome, which can be life-threatening (Hammer, 2007). The increase in the incidence of invasive *S. pyogenes* infection has frequently been associated with specific clones, which raises the
possibility that the rise of particularly virulent clones was responsible for this re-emergence - in particular, the MT1 clone which is dominant among invasive S. pyogenes isolates in most developed countries (Luca-Harari et al., 2009). Variation in the distribution may lead to fluctuations in the severity of infections and in overall mortality rates. S. pyogenes infection may be observed in persons of any age, although the prevalence of infection is higher in children because of the combination of multiple exposures (in schools or nurseries, for example) and host immunity (Martin et al., 2004). The prevalence of pharyngeal infection is highest in children older than three years and has been described as a 'hazard' in school-aged children (Martin et al., 2004). Contemporary data suggested that invasive S. pyogenes infections incidence is around 2 to 4 per 100,000 population in developed countries (Steer et al., 2012).

Numerous observational studies have described the frequencies of potential risk or predisposing factors in patients with invasive S. pyogenes disease, rigorous assessment through analytical means have been limited. The relative importance of these factors may change over time as the prevalence of the acute or chronic predisposing factors changes in frequency, such as influenza activity (Zakikhany et al., 2011). Infection of S. pyogenes in people lacking of teeth causes oral and maxillofacial cellulitis prior to sepsis. In this case, S. pyogenes originated from sinusitis leaked to oral cavity thus, leading to systemic infection through wounding of oral cavity mucosal lining. The study found that, the risk of odontogenic infection still there even among edentulous patients (Inagaki et al., 2017). Penicillin remains the drug of choice for the empirical treatment of S. pyogenes infection, despite over sixty years of use. S. pyogenes has also remained uniformly susceptible to penicillin and resistance towards penicillin or other β-lactams which has been approved for the treatment of S. pyogenes (Spellerberg & Brandt, 2016).

Flaxseed and flaxseed oil (also called linseed oil) originated from the flax plant (Linum usitatissimum). Flaxseed protein extracts have demonstrated antibacterial activities against most tested microorganisms, especially Gram-negative bacteria. Meanwhile, flaxseed oil has been shown to have antibacterial potential against Staphylococcus aureus, Pseudomonas aeruginosa, and Escherichia coli K-12 (Kaithwas et al., 2011). Evidently, flaxseed contains the highest content of lignin and secoisolariciresinol diglucose (SDG) among all grains, and is the richest dietary source of plant-based SDG (Liggins et al., 2000; Zhang & Xu, 2007). Flaxseed derivatives, such as defatted flaxseed meal or flax hulls, have higher concentrations (2.3 % and 4 % respectively) of SDG (Gaafar et al., 2013). Their usage as a dietary supplement is becoming more popular nowadays as a series of researches have highlighted its multitudinous effect on human health. However, there are still a lot of ongoing studies on the means of optimizing the beneficial effects of this called magic plant (Pan et al., 2009).

Nigella sativa L. (Ranunculaceae) – commonly as “black cumin” – is a herbaceous plant that grows in the Mediterranean countries and Turkey. It is known to have therapeutic potential; in fact, sativa-based oils are claimed to have potent anti-inflammatory, anticancer, antidiabetic, antimicrobial, antihistaminic, and antihypotensive effects (Al-Rowais, 2002; Salem, 2005). N. sativa contains many components that have pharmaceutical effects such as: thymohydroquinone, dithymoquinone, thymol, carvacrol, nigelicline, niggellimine-x-oxide, nigellidine, and alpha-hedrinhave (Aljabre et al., 2005). Thymoquinone is one of the main components of N. sativa.
that has anti-microbial, anti-inflammatory, anti-hypertensive, anti-carcinogenic, antioxidant, and hepatoprotective effects (Tariq, 2008 & Ahmad et al., 2013).

The present study has been conducted to evaluate the antibacterial effect of flaxseed and N. sativa extracts against S. pyogenes which is believed to be resistant to different types of antibiotics, the implication of this study will be useful in propagating the use of these natural based products as therapeutic medications.

Materials and Methods

Bacterial strains

Streptococcus pyogenes (ATCC®19615™) was used in this study. The cultures as obtained from the American Type Culture Collection (Manassas, VA, USA). Bacterial strain was stored in tryptic soy broth (TSB) with 20% glycerol at -80°C and used as required. Nutrient agar and nutrient broth (Merck) were used to culture the bacterial strains.

Flaxseed and Nigella sativa extracts

In collaboration with Philadelphia University, 500 grams of flaxseeds were ground using a dried blender and extracted using 99.8% ethanol in a Soxhlet chamber. The extract was collected and evaporated in a rotary evaporator under pressure at 60°C. Freeze-drying of the concentrated extracts was done for about 30 minutes to remove the water residues. The crude extracts were stored at 4°C pending further use.

The extracts of flaxseed were dissolved in 20% of dimethyl sulfoxide (DMSO) and filter-sterilized using a 0.22 μm PES syringe filter. The concentrations of the flaxseed extracts were 1, 5, 10, 20, 50, and 100 mg/ml. All extracts were diluted with DMSO to achieve the desired concentrations. Similar protocol was reflected for N. sativa.

Antimicrobial sensitivity tests

Bacterial growth

The bacteria were cultured on nutrient agar and inoculated in nutrient broth. The plates were incubated at 37°C for 18 to 48 hours. For broth media that were incubated for 24 hours, 10 μl from the bacterial stock was revived at 37°C to be used as the inoculum. The turbidity of the suspensions were adjusted to 1.5 to 3 x 10⁸ cells/ml, which corresponded to an absorbance of 0.08 – 0.10 at a wavelength of 625 nm (Vanessa Maria Fagundes et al., 2014).

Disk diffusion method

The sensitivity of S. pyogenes to the plant extracts was determined via the Kirby-Bauer disk diffusion method (Aqueveque et al., 2006; Bauer et al., 1966; Devi et al., 2011) as well as the European Committee on Antimicrobial Susceptibility Testing (EUCAST) recommendations. The nutrient agar was inoculated by swabbing with a sterile cotton swab that has been soaked in a bacterial broth. With a slight modification from previous studies, aqueous extract with 100 mg/mL concentration were pipetted with different volume (1, 5, 10, 20, 50 and 100 µl) onto sterile blank discs (6 mm diameter (Oxoid, Badhoevedorp, Netherlands) and the discs were allowed to dry in the biosafety cabinet before being impregnated onto agar plate spread with inoculum (Revathi & Malathy, 2013). A standard antibiotic, penicillin was used as positive control for all tested bacteria while DMSO was used as negative controls. All agar plates were incubated in an incubator at 37°C for 18 to 24 hours. The positive control was penicillin while the negative control was DMSO. Susceptibility testing was performed in three biological replicates. The plates were observed for the presence of an inhibition zone. The diameters of the inhibition zones were measured (in mm) for each strain, and the mean values calculated. The absence of
inhibition zone was interpreted as absence of antimicrobial activity.

**Statistical Analysis**

The means and standard errors (SE) were calculated using Microsoft Excel 2010 (Microsoft Corporation, Redmond, CA, USA).

**Result and Discussion**

In this study, flaxseed and *N. sativa* extracts at concentrations of 5 to 100 mg/ml inhibited *S. pyogenes* which was similar to the positive control and this in line with the finding with Warnke *et al.*, (2008). *N. sativa* showed inhibition zones to *S. pyogenes* at > 20 mg/ml concentration. This was similar to Hasan *et al.*, (2013) in which the highest antimicrobial activity was recorded at 100 mg/ml. These plant extracts have considerable activity against Gram-positive bacteria but not Gram-negative (Alhaj *et al.*, 2008).

The biological activities of the compounds from the plant extracts depend on the type of solvent that was used during extraction. The most commonly-used solvents were methanol, ethanol, and water (Parekh *et al.*, 2009). In this study, the inhibition zones produced by the flaxseed and *N. sativa* extracts were not very high probably because of agro-climate factors, handling of the extracts, as well as the phytochemical ingredients of the extracts (Erdman *et al.*, 2007). Most active antimicrobial compounds were soluble in polar rather than nonpolar solvents (Parekh *et al.*, 2009).

We have studied the antimicrobial activities of flaxseed and *N. sativa* extracts of various concentrations against *S. pyogenes*. The results are shown in Table 1. According to Table 1, the diameters of the inhibition zones of *S. pyogenes* in *N. sativa* and flaxseed extracts of 100 mg/ml were 6.33 ± 0.33 mm and 6.00 ± 0.0 mm, respectively. At the lowest concentration of the extracts (1 mg/ml), the diameters were 5.67 ± 0.33 mm and 6.00 ± 0.58 mm, respectively. The experiments were done in triplicates and the results expressed in terms of mean ± SE.

Antibacterial effects were demonstrated by the flaxseed extract at concentrations ranging from 5 to 10 mg/ml. From 20 to 100 mg/ml, the antibacterial effects of the flaxseed extract were the same. Evidently, the lignans of flaxseed (secoisolariciresinol) were effective against *S. aureus* and *Vibrio sp.* (Barbary *et al.*, 2010). The *N. sativa* extract showed antibacterial effects at concentrations ranging from 1 to 100 mg/ml. In this study, it was effective against *S. pyogenes* bacteria. Evidently, a number of plant-derived compounds are more effective against Gram-positive bacteria then Gram-negative bacteria (Morsi, 2000; Ali *et al.*, 2001; Jones *et al.*, 2002).

Table 1. Inhibition zones of *S. pyogenes* in *Nigella sativa* and flaxseed extracts (n=3).
The Minimum Inhibitory Concentration (MIC) of flaxseed, *N. sativa* extracts were determined using resazurin based 96-well plate microdilution method. After the incubation period, columns with no colour changes (blue resazurin colour remain unchanged) were scored as (MIC) value. The result showed that *N. sativa*, flaxseed extract shared the same MIC which was 12.5 mg/ml on *S. pyogenes* (Table 2). Previous studies reported that MIC value for *N. sativa* extract was between <0.25 µg/ml and 1.0 µg/ml of *Staphylococci* species (Ayse *et al.*, 2016 & Magdalena *et al.*, 2014). The difference may be due to the presence of various chemical compounds in this type of extract which affect the results of MIC towards *S. pyogenes*, and this may be due to the method of isolation and fractionation that provides a specific target of bioactive compound with antimicrobial properties (Shrivastava *et al.*, 2011). The antibacterial activity of flaxseed extract is associated with its ability to merge with bacterial cell wall thus, combating bacterial growth. Other than that, the existence of long-chain unsaturated fatty acids such as alpha linolenic acid and linoleic acid might contribute to the antimicrobial therapeutic efficacies of flaxseed (Barbary *et al.*, 2010).

**Conclusion**

In conclusion, flaxseed and *Nigella sativa* extracts have the potential to be developed as antibacterial agents against *S. pyogenes*. However, in this study, the author suggest that these extracts should be explored in vivo to elicit a greater effect to the whole organism systems based on its toxicity, safe dosage as well as its effect on the normal microbiota in the future. Further investigations can be carried out on the synergistic effect since both extracts have good potential to be effective antimicrobial agents in the medical practice.

Instruction to Authors

Submission

Complete manuscripts, written in English along with tables and illustrations should be submitted as softcopy to zainulrajion@iium.edu.my

Conditions

All manuscripts submitted for publication must be accompanied by a cover letter declaring originality of the work and certifies that the manuscript has not been published or submitted elsewhere, free from conflict of interest and conduct of research in accordance to ethical guidelines established for human subjects and animal welfare. In addition, a statement of agreement of all authors to transfer all the copyrights to the journal should also accompany the manuscript.

A copy of the certification form, which certifies that the manuscript has not been published or submitted before and all authors have contributed and are in agreement with the content of the manuscript, must be submitted to the journal’s editorial office by uploading it as a PDF file.

Manuscripts submitted for publication are understood to be offered only to IJOHS and which have not been sent to other journals for consideration. There is no publication fee to submit or publish content in IJOHS.

Manuscript should be typed in Arial, font size 11 with 1.5 spacing.

The manuscript should be divided into the following sections with the sequence; Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Illustrations and Figure Legends must be incorporated near to the text they are cited

Title Page:

Title page should be arranged in the following order: (1) a concise and informative title not exceeding 80 characters; (2) authors’ full names (without degrees and titles) and affiliation including city and country. Superscript numbers may be used to affiliate authors to different departments or institutions; and (3) a complete mailing address, telephone, fax and e-mail address of the corresponding author.

Abstract:

Abstract should be unstructured and should not exceed 250 words. It should be a self-standing summary of the work that may be republished by information retrieval services. A maximum of 5 keywords should be listed at the end of the abstract.

Introduction:

Introduction should briefly and clearly describe the background and objective(s) of the study. Avoid exhaustive review of the literature and include only relevant recent studies.

Materials and Methods:

This section should be described in sufficient details so that it is reproducible. It should include technical information such as the study design, and specific procedures. Sub-headings may be used to enhance the clarity or to categorize the methods. Established methods or procedures should be named and cited. New methods or modifications of old methods should be described with complete details. Authors are advised to use generic names and terms rather than commercial names. Statistical methods applied, software used must also be stated clearly and concisely.

Results:

This section should be presented in a logical sequence in text, tables and illustrations. Subheadings may be used
to enhance clarity or to call attention to the most significant findings. Data appearing in tables or figures may be summarized but not duplicated in the text. Tables and figures should be numbered in the order in which they are described and cited in the text. Example, For tables, examples are Table 1, Table 2 and for figures, examples are Figure 1, Figure 2.

Discussion:
This section should summarize, explain and interpret the results with a scientifically critical view of previously published works in the field. Avoid repetition of the data already presented in the result section.

Acknowledgements:
This section is to be given to those who have provided assistance to the project and sponsors who have given financial support and funds.

References:
This section should list all sources cited in the paper. The citations should be arranged in alphabetical order by the surname of the first author without numbering in the text. Cite article as e.g. (Ahmad, 2016) for a single author, (Chu & Kim, 2019) for two authors and (Karim et al., 2013) for more than three authors.

Standard journal article
References to journals should provide the name(s) of the author(s), year, title of the paper and journal, volume and issue number, page numbers. Please provide full name of journal. If there are more than six authors, the first six authors should be listed and followed by et al. in the list of References.

Book
References to books/monographs should give the name(s) of the author(s), year, title of book, edition number, place of publication, publisher and page numbers.

Chapter in book
References to chapter in books/monographs should give the name(s) of the author(s), year, chapter title, editors, title of book, edition number, place of publication, publisher and page numbers.

Internet resources
Authors are required to include as much electronic retrieval information as needed for others to locate the sources they have cited.

Tables
Each table should have a suitable title with footnotes wherever necessary. Do not use vertical lines in the table.

Illustrations
All figures and illustrations could be original photographs, artwork or high-quality digital images (submitted as CMYK - 8 bits per channel in TIFF format). Images must be at least 600 by 450 pixels (proportional height) in size when in landscape orientation with a resolution of at least 300 pixels per inch. Graphs should be approximately 500 pixels wide so that all labeling can be read with data points clearly visible. Figures should be numbered
consecutively in the order in which they appear in the manuscript, using Arabic numerals. A list of figure legends must be included on a separate page following the illustrations. The legend should explain each figure in detail. All figures will be printed as black and white. Colour figures will only appear in the PDF file.

**Page proofs**

On acceptance of the manuscripts for publication, page proofs should be reviewed meticulously by the contributors. Changes made in proof should be limited to the correction of typographical errors. Proofs must be returned for publication with corrections and responses to queries on the date specified by the Editor.
