### Abstract

∨ View references (34)

The plant *Psychotria malayana* Jack belongs to the Rubiaceae family and is known in Malaysia as “meroyan sakit/salung”. A rapid analytical technique to facilitate the evaluation of the *P. malayana* leaves' quality has not been well-established yet. This work aimed therefore to develop a validated analytical technique in order to predict the alpha-glucosidase inhibitory action (AGI) of *P. malayana* leaves, applying a Fourier Transform Infrared Spectroscopy (FTIR) fingerprint and utilizing an orthogonal partial least square (OPLS). The dried leaf extracts were prepared by sonication of different ratios of methanol-water solvent (0, 25, 50, 75, and 100% v/v) prior to the assessment of alpha-glucosidase inhibition (AGI) and the following infrared spectroscopy. The correlation between the biological activity and the spectral data was evaluated using multivariate data analysis (MVDA). The 100% methanol extract possessed the highest inhibitory activity against the alpha-glucosidase ( $IC_{50}$   $2.83 \pm 0.32$   $\mu$ g/mL). Different bioactive functional groups, including hydroxyl (O-H), alkenyl (C=C), methylene (C-H), carbonyl (C=O), and secondary amine (N-H) groups, were detected by the multivariate analysis. These functional groups actively induced the alpha-glucosidase inhibition effect. This finding demonstrated the spectrum profile of the FTIR for the natural herb *P. malayana* Jack, further confirming its medicinal value. The developed validated model can be used to predict the AGI of *P. malayana*, which will be useful as a tool in the plant's quality control. © 2020 by the authors.
